Human Biochemistry. By Israel S. Kleiner, Ph.D., Professor of Biochemistry and Director of the Department of Physiology and Biochemistry, New York Medical College, Flower and Fifth Ave. Hospitals, New York. Second edition. Cloth. Price, \$7. Pp. 649, with 77 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1948.

The practice of medicine today is difficult without some understanding of human biochemistry. Often the books that are prepared are intended more for the medical student and chemical student than for the practitioner; such books are too technical for the audience that could use them to considerable advantage. This volume does not provide so much detail that the reader becomes lost in the pages. It offers comparatively brief discussions that can be quickly read and easily understood. Included in the chapters are discussions on physical chemistry, carbohydrates, lipids, proteins, body tissues, milk, blood, enzymes, digestion, chemical changes within the large intestine, vitamins, foods, physiologic oxidations, nitrogen metabolism, carbohydrate metabolism, lipid metabolism, mineral metabolism and water balance, urine, the chemistry of respiration and acid-base balance, energy metabolism, changes in the chemical composition of blood, hormones, and certain clinical applications which involve function tests and other problems of clinical significance.

Formulary Bellevue Hospital. (Prepared by Bellevue Hospital Committee on Drugs and Formulary.) Dr. Edward L. Bernecker, Commissioner, Department of Hospitals, City of New York. Dr. William F. Jacobs, Medical Superintendent, Bellevue Hospital, New York. Paper. Pp. 72. The New York Physician, 1440 Broadway, New York 18, 1948.

This formulary lists the agents found acceptable by the Bellevue Hospital Committee on Drugs and Formulary for the dispensing of drugs to treat patients at Bellevue Hospital. The purpose of the formulary is "first, to assure that the patients treated at Bellevue Hospital are given the benefit of the most effective and accepted therapy; second, the institution, because of its vast teaching facilities, has the obligation to the physician to have available to him the most recent advances in therapy." The formulary is not a textbook of therapeutics or pharmacology, and provides no indication of the therapeutic use of the contained drugs. This is the way hospital formularies should be prepared, and the committee is right in feeling "strongly that no one should use a drug until he is thoroughly familiar with its pharmacologic action, therapeutic indications, dosage, and signs of toxicity. Such information could never be adequately contained in a pocket Formulary." However, a therapeutic classification, offered as a guide only, is included at the end of the formulary. This booklet is an adequate testimony to what can result from a careful study of drugs that are used in a hospital and the formation of a formulary committee to assure the proper use of these drugs.

Practical Orthodontics. (Original Text by the Late Martin Dewey.) Revised by George M. Anderson, D.D.S., Professor of Orthodontics, Baltimore College of Dental Surgery, Baltimore. With Chapters by Bernhard Wolf Weinberger and others. Seventh edition. Cloth. Price, \$10. Pp. 556, with 640 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1948.

There is much valuable fundamental material covered by the seventh edition of this book. It contains a chapter on the field of orthodontics as a dental specialty, including definitions, objectives and benefits of this science. There is an inclusive and pertinent history on the background and progress of modern orthodontics. The volume continues with lengthy discussions on etiology, diagnosis, classification and the mechanical methods of treatment and retention of malocclusions of the teeth. A parallel is drawn between medical and orthodontic diagnosis. The former is generally concerned with a pathologic condition and is determined symptomatically or by the exclusion of other diseases. Orthodontics for the most part does not involve a pathologic condition, but presents a problem in diagnosis concerned with growth and development (or lack of) of the body as a whole, and the teeth, jaws and face in particular. In its own field each has the same importance in relation to prognosis and treatment. Fortunately for orthodontics, the diagnosis need not be made in haste, but periodic observation gives a splendid opportunity to observe the growth pattern, habits and general

health of the patient. While there is a chapter by Broadbent on his original roentgenographic cephalometric growth studies, there is not a discussion of the clinical application of cephalometrics to case analysis and treatment planning as used by Downs, Thompson and Wylie and others. There is no comprehensive discussion on the growth of the mandible, its effect on the denture pattern and the influence of mandibular rest position on case analysis and treatment planning. A chapter is devoted to extraction in its relation to orthodontic treatment. The profession has generally been divided into three classes in their attitude toward this subject, and the author attempts to show that there is a place for extraction in orthodontics but warns that if the privilege is abused by poor judgment, the removal of teeth will produce its repercussions and poor results. This book is a fine source of information and is considered to be one of the five or six standard texts in the field of orthodontics.

The Netherlands Red Cross Feedingteam Report on Nutritional Survey in the Netherlands East Indies Conducted During October 1945 till June 1946. Boards. Pp. 119, with illustrations. Netherlands Red Cross Society, The Hague, 1948.

Immediately on the capitulation of Japan a Netherlands Red Cross Nutrition Research Team was organized, and within a week an advance contingent was on its way to Java. There they found chaos but set to work to aid and to study the large population groups malnourished after years of life in military internment camps and prisons. This report of their work is a valuable contribution to our knowledge of nutrition, of tropical disease and the problems of organized medical relief work. A large part of the report, which reflects the orientation of the research program, is concerned with the laboratory evaluation of the state of vitamin nutrition, but the notes on clinical findings are perhaps more interesting. Simple caloric deficiency was not extreme, but the results of prolonged malnutrition were numerous and puzzling. Many unexpected problems arose and some of these were solved by ingenious improvisation. The high infant mortality was checked by a "wonder milk" produced from dried milk by bacterial culture. The forensic medical problem of appraising the evidence in suspected cannibalism was solved by a study of the crystals formed in congealing fat. However, as in other contemporary studies on famine victims, the recognition of unsolved problems is perhaps the most important feature of the report. The lack of vascular, thermal and other reactions of standard stimuli in the underfed, combined with the disappearance of allergic complaints, poses problems—and perhaps gives a clue to their study—which have many ramifications.

The Story of the Johns Hopkins: Four Great Doctors and the Medical School They Created. By Bertram M. Bernheim, M.D. Cloth. Price, \$3.50. Pp. 235, with 10 illustrations. Whittlesey House, McGraw-Hill Book Company, Inc., 320 W. 42d St., New York 18, 1948.

A story of the development of Johns Hopkins Medical School from 1889 to the present day with particular emphasis placed on human interest. The author states that he has been associated with the school for the past fifty years. The book deals with the founding and subsequent development of the Johns Hopkins Medical School and Hospital. Development is related to the lives of its four best known founders, Dr. W. H. Welch, Dr. W. Osler, Dr. W. Halsted and Dr. H. Kelly. The lives of these men, who contributed to the flowering of Johns Hopkins Institution, and the near and distant impact of the traditions of Johns Hopkins on medicine are described. Chapters are devoted to special historical occurrences at Johns Hopkins, such as the admission of women, the development of the resident system, Harvey Cushing and the Hunterian laboratory, and development of the "Welch Institute of the History of Medicine." Contributions of other men are mentioned, such as Hugh Young, in urology, J. W. Williams in obstetrics and M. T. Finney in surgery.

A chapter is devoted to the decision of Johns Hopkins to adopt complete full time employment of physicians with comment on the probable effect of this decision on the future of the institution.

Much of the material is of interest to all physicians, particularly the chapters which refer to the four outstanding founders of Johns Hopkins. Other sections will interest only those associated with Johns Hopkins, as former students or staff.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

HEREDITY AND TUBERCULOSIS

To the Editor:—Do children born of tuberculous parents have a hereditary susceptibility or a tuberculous diathesis?

Edward K. Disney, M.D., Outwood, Ky.

ANSWER.—Scientific evidence does not justify the belief that children born of tuberculous parents have a hereditary susceptibility or a tuberculous diathesis. Expressions to that effect are based entirely on personal opinion. Galen (131-201 A. D.) was of the opinion that approximately one half of the cases of tuberculosis were due to heredity and the other half to contagion. He became the authority in medicine for the next 1,500 years, or until the Renaissance in medicine. Throughout these centuries there were two schools of thought, one clinging to the hereditary nature of tuberculosis, and the other to its contagiousness. The school believing in the contagious nature of tuberculosis became strong enough to cause the enactment of laws in Italy and Spain in the last half of the eighteenth century to control the contagiousness of the disease. The inheritance theory became so firmly implanted in the human mind, however, that it has been carried down to the present day despite the overwhelming evidence that the disease is caused by a micro-organism, and therefore is contagious, and the total lack of scientific evidence for inheritance.

Even congenital tuberculosis is relatively rare, as determined by necropsy examination of stillborn infants and those who die from various causes soon after birth. It is a great rarity for a newborn infant to react to tuberculin. Chadwick administered the test to 156 newborn infants of tuberculous mothers, and not one reacted. Apparently congenital tuberculosis occurs only when the placenta becomes involved so that its barrier effect is lost.

Early in this century Grancher of France demonstrated that when infants did not have contact with their tuberculous mothers after birth but were placed in foster homes they did not subsequently contract more tuberculosis than the children of the general population. This observation has been confirmed many times. Children of tuberculous mothers or fathers do contract more tuberculosis than those of the general population if they remain in contact with the parents. Children of tuberculous parents who do not have contact with the parents after birth but who at some subsequent time are exposed to contagion do not contract more primary tuberculosis than children under the same circumstances of parents not having tuberculosis. Moreover, the children of tuberculous parents who subsequently have primary lesions are not more likely to have the acute and chronic reinfection forms of the disease than are those from homes where there is a total absence of tuberculosis.

The theories which permit the fatalistic point of view that the child of tuberculous parents is more susceptible to tuberculosis because of heredity, or the opposite, that the child of nontuberculous ancestry is more susceptible because of the absence of inherited immunity, are untenable. The entire problem resolves itself into one of infection with tubercle bacilli, which usually occurs after birth. All children have an effective defense mechanism against the first invasion with this organism. However, this is not adequate to destroy tubercle bacilli, and thus some of them subsequently have acute and chronic reinfection forms of clinical tuberculosis, regardless of the presence or absence of this disease in their ancestors.

POSTNASAL DISCHARGE

To the Editor:—What are the common causes of "postnasal drip"? What are the most successful ways of treating this condition? Is antrum lavage of benefit?

M.D., New York.

ANSWER.—"Postnasal drip" is the term used to describe the chronic accumulation of secretion in the nasopharynx, from where it may "drip" down into the pharynx. Such secretions usually originate in the nose or sinuses and are carried back by the ciliary mechanisms into the nasopharynx. There are several

possible causes for such an accumulation, some of which are chronic inflammatory states in the nose and sinuses caused, for example, by infections or irritants, allergic reactions in the nose or a simple vasomotor response either to external, systemic or neurogenic factors.

Antrum lavage is indicated only when the antrum is the site of chronic infection and retains an accumulation of secretion which may thus be removed. The recovery of ciliary action and normal emptying of the sinus is thereby promoted.

HYPOCHLOREMIA

To the Editor:—A paracentesis was performed on a 45 year old patient with nodular cirrhosis; 2,000 cc. of fluid was removed and the wound allowed to drain. After four days extreme weakness developed and the patient could "hardly lift his glass of water." Blood chlorides were 120 mg. per hundred cubic centimeters and nonprotein nitrogen 120 mg. The patient was given 13 Gm. of sodium chloride intravenously and by mouth that day, and in a few hours his strength and general appearance improved. Chlorides and nonprotein nitrogen returned to normal in three days. There has not been a recurrence. The patient had been on a salt-poor diet previous to this episode. He does not have findings suggestive of Addison's disease. What explanation can be offered for this and what future care is suggested?

M.D., New Jersey.

ANSWER.—It has recently been shown that a considerable shift of chloride ion into extracellular spaces may occur in primary hepatic disease, but it is rare to find any significant depression in blood chlorides. However, after tapping in cirrhosis, a significant hyponatremia may develop which is frequently masked by hemoconcentration (Cantarow, A.: *Am. J. Clin. Path.* 8:142-152 [March] 1938). It is certainly most unusual to encounter a chloride deficiency of this degree in a cirrhotic patient, and, unless the laboratory methods employed are known and whether the determinations were made on whole blood or serum, it would be impossible to reduce the deficiency to terms of milliequivalents per liter. The amount of sodium chloride (13 Gm.) which was required to relieve the patient's symptoms and bring the blood chlorides to a normal level is rather small, a fact which indicates the possibility of a laboratory error.

It would seem advisable to observe the blood chloride levels in this case before and after tapping, while the patient is taking a normal amount of sodium chloride. Calculation of the chlorides in the ascitic fluid and hematocrit readings on the patient's blood would then permit a fairly accurate appraisal of the chloride losses. This would, of course, simplify the problem of replacement of chlorides.

TREATMENT OF MENOPAUSE

To the Editor:—A white woman aged 50, nulliparous, has had menopausal symptoms for the past ten years. She began menses at age 11 and had severe dysmenorrhea until her late twenties, at which time the dysmenorrhea abated somewhat. Her menstrual periods were frequent, beginning with seven day intervals and advancing to twenty-one day intervals at 30 years of age. At age 40 she had irregular menses and hot flashes. In 1943 she had only two menstrual periods. She was given estrone every three weeks for nine weeks. At the end of this time she flowed profusely and the therapy was discontinued. In 1946 she had estrogen therapy and flowed profusely each time after receiving 10,000 units. In January 1947 she took diethylstilbestrol 0.5 mg. every three or four days. She did not flow but had the sensation of impending menstruation. I saw her on Nov. 6, 1948, for the first time. She continues to complain of hot flashes, nervousness and headaches. Her last menstrual period was in October 1943. Pelvic examination is negative. What therapy can be recommended?

M.D., Nebraska.

ANSWER.—A patient bleeding as irregularly as the patient mentioned deserves a diagnostic curettage for diagnosis. Following this determination of basal metabolic rate and cholesterol should be performed to determine thyroid function. If these are normal or subnormal give thyroid to tolerance starting with ½ grain (30 mg.) and raising it ½ grain every three to four weeks until the morning pulse rate before arising is just under 80.

Phenobarbital, ½ grain one to three times a day, will help remarkably.

If curettings are negative for carcinoma, then the patient can be started on 1 mg. diethylstilbestrol a day until symptoms are relieved, but not for more than thirty days. The dose then should gradually be cut down to the least compatible with symptom abatement. Many physicians believe that estrogen should not be given more than about three fourths of the time; that is, give it for twenty-one days, stop for ten days, and then start again.

It must be remembered that not all patients with the symptoms complained of are suffering from menopause. A large psychic factor occurs.

HEREDITY IN EPILEPSY

To the Editor:—A couple consulted me as to the advisability of parenthood. They are both 30 years of age and are second cousins (grandfathers were brothers; mother of wife and father of husband are first cousins). There is a history of grand mal epileptic seizures in the wife's father, her father's brother and sister. Epilepsy does not occur on the husband's side. Would the chances of epileptic offspring be influenced by the family interrelationship? What are the chances of the parents' having an epileptic child and also the chances of future development of epilepsy in the wife?

T. E. Swegart, M.D., Maquoketa, Iowa.

ANSWER:—Because the wife's blood relationship to her husband was through her mother, and not through her father (the epileptic), consanguinity would not add anything to the chances of epilepsy in the children of the couple named. The wife's father is the only affected limb of the family tree. Information is lacking about any family history of migraine, or whether some acquired condition might have been responsible for the epilepsy of the father, uncle and aunt of the wife. At the age of 30 her chances of having clinical symptoms are slight, certainly much less than the 1 in 40 chance of the average near relative of an epileptic. If the husband does not carry a predisposition, the chances of their having an affected child are reduced still further. Electroencephalograms of the couple might define the chances more clearly (Lennox, W. G.: *Marriage and Children for the Epileptic*, *Human Fertil.* 10: 97-106 [Dec.] 1945).

PERMANENT BRAWNY EDEMA

To the Editor:—A 33 year old para III gravida III has had massive pitting edema of the entire leg from thigh to foot since an attack of phlebitis following the birth of her first child in 1938. The edema is greater in the left leg and fluctuates somewhat from day to day. Signs of cardiovascular disease are absent. What treatment is recommended?

M.D., Indiana.

ANSWER:—The condition is difficult to improve if the usual methods have been tried and have failed. Usual methods consist of bed rest for several days with leg elevated, full length elastic stockings (made to order by fitting when swelling is least) whenever patient is up and bed rest twice a day for one hour with leg elevated.

If the swelling can be decreased scar tissue is less likely to form in the edematous tissue. Such fibroblastic proliferation causes the permanent brawny edema.

Any suspicion of dermatophytosis between the toes must be treated thoroughly with fungicides. Veins should not be injected with sclerosing solutions and should not be ligated, because venous collaterals should be preserved. If much brawny edema has already formed the treatment is surgical. The Kondoleon operation consists of removal of large amounts of such tissue.

TREATMENT OF BREAST AMPUTEES DURING PREGNANCY

To the Editor:—A patient, para III, about four months pregnant, had both breasts amputated because of hypertrophy in 1944. Diagnosis was unknown by the patient. She has some breast tissue at present and is beginning to become uncomfortable. What type of treatment should be given to this patient?

J. B. Carlyle, M.D., Burlington, N. C.

ANSWER:—The breasts usually stop developing during pregnancy between three and four months; therefore treatment is not necessary now. At delivery start the patient on 5 mg. of diethylstilbestrol each night at bedtime for four or five nights and use an ice bag if pain develops. Limit fluid intake moderately.

Breast tissue without ducts is common in the axilla during pregnancy, and the described treatment is usually all that is necessary.

EDEMA OF RETINA

To the Editor:—A month ago a 37 year old man looked at a telephone pole and noticed that it seemed to bow much to his left if he used his left eye only. Straight edges seemed to bow down when the same eye was used. After correction of mild hyperopia, astigmatism and exophoria for far range, bowing in both directions remained the same. Retinoscopic examination was normal. History of injury is absent. The patient complains of mild pain near the left temple and in the left occiput. Please suggest diagnosis and treatment.

O. C. Amstutz, M.D., Bellefontaine, Ohio.

ANSWER:—The image distortion suggests a localized elevation or edema of the retina near the fovea, probably immediately superior and nasal to it. This may occur in early choroiditis, retinal detachment, macular edema or cyst. Such lesions may be almost impossible to detect except by ophthalmoscopy with red-free light. Treatment must be directed toward the cause.

VERTIGO FROM STREPTOMYCIN

To the Editor:—A patient with draining tuberculous sinuses (inguinal and posterior 'liac) of twenty years' duration was treated with 1 Gm. of streptomycin daily. Streptomycin was discontinued after fifteen days because of severe vertigo. The sinuses are healed. After three weeks the eighth nerve impairment seems to be improving. Is there any therapy for relief from this vertigo? If the sinuses reoccur would another course of streptomycin be advisable, assuming a recovery from the present vestibular dysfunction?

W. W. Montgomery, M.D., West Rutland, Vt.

ANSWER:—Therapy for the relief of vertigo following damage by streptomycin to the vestibular apparatus is not known. However, it has been found that after a few months, even without regeneration of the vestibular nerve, the patient improves greatly because of cerebellar compensation.

Recurrence of the draining sinuses once healing has taken place is unusual. However, dihydrostreptomycin in equal dosage has proved to be equally effective, and less toxic in its action over a longer period of time. A dosage of 0.5 Gm. daily is probably as effective in the treatment of draining tuberculous sinuses as 1 Gm.

OPTICAL LENSES

To the Editor:—What methods may be used to determine the qualities of optical lenses in spectacles needed for good vision? What apparatus can be used in the office to make such tests?

Joseph Bagan, M.D., Washington, D. C.

ANSWER:—Ophthalmologists do not regularly use precise methods to determine whether or not the optical lenses which they prescribe for patients have special qualities suitable for good vision. The manufacturers all supply lenses which are perfectly adequate. Even glass which has aged through many years of exposure to the sun's rays and has acquired a slight yellowish color apparently does not prevent the patient from seeing just as well, in every detail, as he can through brand new glass. The Bureau of Standards, Washington, D. C., can furnish further detailed information.

HYDROCEPHALUS

To the Editor:—In *Queries and Minor Notes* (The Journal, January 15, p. 194) the question was asked whether occurrence of hydrocephalus or other abnormalities in one child might indicate probable occurrence of abnormalities in subsequent offspring of the same woman.

The answer stated that a subsequent child might suffer from hydrocephalus, that this was extremely unlikely to occur but that hydrocephalus had been observed in several members of the same family. In the absence of a family history of hydrocephalus, the advice was given that, in having additional children, the parents of a hydrocephalic child run no greater risk in having another hydrocephalic child than do all other parents.

Murphy (Murphy, D. P.: *Congenital Malformations: A Study of Parental Characteristics with Special Reference to the Reproductive Process*, ed. 2, Philadelphia, J. B. Lippincott Co., 1947) studied the outcome of all conceptions of 890 women, each of whom had given birth to a congenitally malformed child.

He discovered 1 malformed brother or sister in every 8 who were born alive after the birth of the first defective child. In the general population he found only 1 malformed child for every 200 infants that were born alive. Translated into other terms, a mother of a congenitally malformed child, irrespective of the type of defect, is twenty-five times more likely to have another defective offspring than is a mother in the general population.

Anomalies of the central nervous system represented 60 per cent of all of the body defects which Murphy studied, and hydrocephalus accounted for nearly half of these.

Forty of the 890 original families had 2 or more defective offspring. Nine of these 40 families contained hydrocephalic children. Seven of the 9 families each had 2 hydrocephalic children. Four of these 9 families each had an anencephalic child, and 2 of the 4 families had 2 anencephalic children in addition to a hydrocephalic one.

Murphy's study showed also that there is nearly 1 chance in 2 that a subsequent malformed child will exhibit the same defect as that possessed by its earlier born defective brother or sister. This is a high frequency for the reduplication of a defect in a family in view of the great variety of anomalies which may appear at birth.

In view of these observations, and also because, in many instances, normal brothers and sisters resemble one another in many respects, the outlook for the birth of normal offspring does not appear to be as bright for the parents of a hydrocephalic child as for parents in the general population.

Douglas P. Murphy, M.D., Philadelphia.

To the Editor:—I have delivered babies with mongolism. One baby was the second child in a family in which the previous child was normal. The second baby was the third child in a family in which the first child was mongolian and the second child normal. The third baby was the fifth child in a family where the first child was normal, the second had mongolism, the third and fourth children were normal and the fifth had mongolism.

These children have all been seen by recognized pediatricians.

In my experience mongolism does appear more than once in the same family.

ESSENTIAL HYPERTENSION

Laboratory Studies in Human Beings with Drugs Recently Introduced

ROBERT W. WILKINS, M.D.
EDWARD D. FREIS, M.D.
and
JOSEPH R. STANTON, M.D.
Boston

The urgent need for satisfactory medicinal therapy in essential hypertension has led to the investigation of a wide variety of pharmacologic agents. In this clinic, particular emphasis has been laid on the elucidation of the mode of action of the various drugs employed, in the hope of providing a rational basis for the chemotherapy of the disease.

Of the preparations tried in this clinic,¹ two have appeared to be of sufficient practical value to warrant detailed study. These are veratrum viride, the administration of which leads to generalized but integrated vasodilatation, and dihydroergocornine, which inhibits sympathetic vasoconstriction. Effective by mouth, and adequately lasting in action, both are suitable for long term clinical trial. Unfortunately, administration of veratrum often leads to nausea and vomiting, and occasionally to collapse, especially when dosage is not carefully controlled. Therefore, its clinical use frequently is restricted to patients with severe hypertension in whom the benefits warrant the occasional unpleasant side effects. Likewise, dihydroergocornine, while fulfilling many of the criteria of a desirable sympatholytic agent, including oral effectiveness, is of limited clinical usefulness because it lowers the arterial pressure in only a small proportion of hypertensive patients. However, in spite of these shortcomings, both drugs have been of sufficient aid in the management of some cases of severe hypertension to merit investigation of their pharmacologic properties and physiologic effects in normal and hypertensive subjects.

From the Evans Memorial, Massachusetts Memorial Hospitals, and the Department of Medicine, Boston University School of Medicine, Boston. These studies were supported in part by grants in aid from the Squibb Institute for Medical Research and from the Dart Foundation.

Read in a Symposium on Hypertension in a joint meeting of the Section on Experimental Medicine and the Section on Internal Medicine at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 25, 1948.

VERATRUM VIRIDE

This controversial drug, of ancient vintage, has had a colorful history. Used intermittently in the past by obstetricians and general practitioners, it has only recently been made available in a fairly stable, biologically standardized, oral preparation (vertavis®)² suitable for clinical trial in essential hypertension. Its most dramatic hypotensive effect occurs on acute administration and is particularly useful in cases of encephalopathy and/or myocardial failure secondary to severe hypertensive crisis.^{1c}

Since veratrum viride has long been presumed to be a cardiac depressant, laboratory studies of cardiac output under controlled conditions seemed necessary.³ Measured by the Fick method, cardiac output was never found to be decreased, but occasionally to be moderately increased after the drug, particularly in 2 patients in whom it was already low as a result of acute left ventricular failure (fig. 1). In these patients the increase in cardiac output after the drug was taken was associated with a striking reduction in pulmonary arterial pressure, a slowing of the pulse rate and a disappearance of pulsus alternans. A similar disappearance of pulsus alternans was also observed in 3 other patients after the administration of the drug and usually was associated with an improvement in the ballistocardiogram (fig. 2).

In order to corroborate the evidence of a decrease in peripheral resistance after administration of veratrum and also to determine its location, blood flow through various body areas was determined. Since blood flow varies directly with arterial pressure and indirectly with resistance, one would expect the flow to be increased or unchanged, if peripheral resistance is reduced after administration of veratrum, despite the resultant decrease in arterial pressure. Estimations of hepatic-portal (splanchnic, exclusive of renal and adrenal) blood flow by the sulfobromophthalein sodium method⁴ showed an initial reduction to occur with the first fall in arterial pressure, followed by a rise to or above the control values when the lowered arterial pressure became stabilized after a parenteral dose of the drug (fig. 3).⁵ Peripheral blood flow (plethysmographic) in the forearm and calf⁶ was found initially to increase,

2. The vertavis® used in this study was supplied by the Irwin-Neisler Co., Decatur, Ill., and the dihydrogenated alkaloids of the ergotoxine group by the Sandoz Chemical Works, Inc., New York.

decrease or remain the same in the falling phase of the hypotensive response to veratrum, but usually to return to or above control levels in the stable phase.

Likewise, measurements of renal blood flow with para-amino-hippurate (sodium) (PAH) revealed an

Fig. 1.—Chart of cardiac output, systemic arterial pressure (with double systolic readings denoting the amount of pulsus alternans), pulmonary arterial pressure and pulse rate in a hypertensive patient before and after the parenteral administration of veratrum viride (veratrone,® Parke, Davis & Company).

initial decrease, then a return to control values when arterial pressure was established at a lower level after administration of veratrum (fig. 4).⁷ Although cerebral blood flow has not yet been measured, examination of the optic fundi confirmed the observations of Willson

BEFORE DRUG

AFTER DRUG

Fig. 2.—Optical records of the ballistocardiogram and the arterial pressure (Hamilton) of a hypertensive patient before and after the parenteral administration of veratrum viride (veratrone®).

and Smith⁸ that visible arterial and arteriolar dilatation may occur in the retinal blood vessels after administration of veratrum. Thus, in all of the areas where blood

flow was estimated, there was evidence, after an initial adjustment period, of a decrease in peripheral resistance, indicating that the vasodilating effects of the drug were not confined to any one area, but were generalized.

The outstanding change in renal function following the parenteral injection of veratrum viride⁷ was the development of oliguria, a phenomenon which could not be explained by a decrease in either renal plasma flow or glomerular filtration rate. Following an early and usually moderate decrease in filtration rate (inulin) and plasma flow (PAH) there was a return of these functions to or above control levels despite a continuance of the hypotension and the oliguria. While the concentration of the clearance substances in the plasma did not rise, their concentration in the urine was greatly increased during the period of oliguria. However, the renal extraction of PAH as measured directly in renal venous blood was not significantly changed. These results were interpreted as indicating that the kidneys were clearing the blood as efficiently after administration of veratrum as before, but were doing so by the production of a small volume of highly concentrated urine. The antidiuretic effect of veratrum seemed to be temporary, since continuous oral administration of

Fig. 3.—Chart of estimated hepatic-portal blood flow (BSP) and arterial pressure in a hypertensive patient before and after veratrum viride (veratrone®) given parenterally.

the drug did not result in oliguria, even with sustained reductions of arterial pressure.

Vascular distention during venous congestion⁹ in the forearm and calf was usually increased after administration of veratrum.¹⁰ Skin temperature in the hands and feet showed no significant change, and vasomotor responses to "noxious" stimuli remained intact. Likewise, vasopressor overshoots of arterial pressure in response to blood pressure lowering procedures¹¹ were maintained (fig. 5),¹² and postural hypotension did not develop following subtoxic doses of the drug. Finally, atropine, while abolishing the bradycardia commonly found after administration of veratrum, did not block the hypotensive effects.¹⁴ Thus, there was no evidence that the hypotensive action of veratrum was primarily either sympatholytic or parasympathomimetic as defined by

these criteria. Nevertheless, it is of considerable interest that the available pharmacologic evidence in animals¹³ indicates that the vasodilating action of the veratrum alkaloids is mediated over nervous pathways. This suggests that functions of the nervous system other than sympathetic vasoconstriction and parasympathetic vasodilatation may play a part in controlling peripheral vascular resistance and in regulating blood pressure.

DIHYDROERGOCORNINE

Dihydroergocornine (DHO 180, Sandoz Chemical Works, Inc.) has been found to have a hypotensive effect in some hypertensive patients when administered parenterally or orally.¹⁴ In contrast to veratrum, however, it has a clearcut sympatholytic effect. This is demonstrable most readily by the production of postural hypotension which differs from that produced by such agents as tetra-ethyl ammonium salts (TEA) in being seldom accompanied with significant tachycardia.

Sympatholysis after administration of dihydroergocornine was also evidenced by the abolition or decided diminution of vasopressor overshoot responses to blood-pressure-lowering procedures (fig. 6), similar to that observed after surgical sympathectomy¹¹ or the use

Fig. 4.—Chart of renal plasma flow (PAH) and arterial pressure in a hypertensive patient before and after veratrum viride (veratrone®) given parenterally.

of other sympatholytic drugs.¹² In occasional patients its sympatholytic effect was also seen in a rise in skin temperature, in a decrease of vasoconstrictor reflexes in the fingers and toes⁶ and in the inhibition of the cold pressor response.¹² However, there was no constant relationship between its hypotensive effects on the basal arterial pressure and its sympatholytic actions in the extremities. On the other hand, there was in general a good correlation between its basal hypotensive and its postural hypotensive effects. In any case, the hypotensive activity of dihydroergocornine was unpredictable, being negligible in some subjects and profound in others regardless of the route of administration.

After administration of dihydroergocornine the cardiac output (Fick), when measured in both normotensive and hypertensive subjects, was found to be either essentially unchanged or moderately increased (fig. 7).¹⁵ In contrast to the cardioacceleratory effect often seen after TEA, the pulse rate was usually slowed.

15. Freis and others.¹⁴ Halperin, Freis, Culbertson and Wilkins.¹⁶

Hepatic-portal blood flow decreased (fig. 8), especially when the arterial pressure dropped precipitously. In some cases, it subsequently returned toward the control levels.¹⁶ Renal blood flow likewise decreased early and rose again during the stable phase of the hypotensive action of the drug.⁷

Fig. 5.—Optical records of arterial and expiratory pressures (Hamilton) in a hypertensive patient performing the Valsalva maneuver before, five minutes after and twenty-eight minutes after the parenteral administration of veratrum viride (veratrone®).

Peripheral blood flow in the arms and legs (plethysmographic) either increased or remained essentially unchanged after administration of dihydroergocornine.⁶ However, during venous congestion in these areas vascular distention showed a decided decrease,^{10b} in contrast with the decrease found after administration of veratrum.

COMMENT

The studies reported here and elsewhere¹⁶ on the physiologic effects of veratrum and of dihydroergocornine reveal both to be agents that may cause a reduction of arterial pressure with an associated decrease in total peripheral resistance. It is interesting that two drugs as fundamentally different (as judged

Fig. 6.—Optical records of respiration (inspiration down) and systemic arterial, pulmonary arterial, and expiratory pressures (Hamilton) in a hypertensive patient performing the Valsalva maneuver before and after the parenteral administration of dihydroergocornine.

by animal experiments and the present results) should have similar hemodynamic effects, both sequentially and selectively. Possibly this explains their apparent syner-

Freis and others.¹⁴ Freis, Stanton and Wilkins.^{14a} Freis and others.^{14b} Halperin, Freis, Culbertson and Wilkins.¹⁶ Culbertson and others.^{16a} Litter, Freis and Wilkins.⁹ Freis and others.⁷ Litter and Wilkins.⁹ Litter and Wilkins.^{10b} Wilkins and others.¹⁴ Wilkins, Freis, Stanton and Culbertson.¹² Krayer and Acheson.¹³ Bluntschli.^{14b} Bluntschli and Goetz.^{14c}

gistic, or additive, effects when administered together to certain hypertensive patients.¹⁷ Furthermore, it is of interest and possibly of importance that both drugs, though acting by different mechanisms, do so through the central nervous system. In this respect they differ from other vasodilator drugs, such as the nitrite group, and from other sympatholytic agents, such as dibena-

Fig. 7.—Chart of cardiac output (Fick) and arterial pressure (Hamilton) in a hypertensive patient before and after parenteral administration of dihydroergocornine.

mine® (N,N-dibenzyl-beta-chloroethylamine) and the tetraethyl ammonium salts, which are said to act peripherally.

The results so far with these drugs appear to indicate that their primary action in lowering the arterial pressure is to change relationships in the blood-pressure-regulating and integrating mechanisms in the central nervous system. As a result of this and perhaps also of their peripheral vasodilating effects, blood flow in the various organs becomes readjusted so as not to be seriously compromised by the lowering of arterial pressure. This allows an adequate venous return of blood to maintain cardiac output. The slowing of heart rate pre-

Fig. 8.—Chart of renal plasma flow (para-amino-hippurate sodium), hepatic-portal blood flow (Sulfobromophthalein Sodium), and arterial pressure (Hamilton) in a hypertensive patient before and after the parenteral administration of dihydroergocornine.

vents the tachycardia and palpitation that ordinarily result from reflexes arising in the aortic and carotid sinus areas when such a lowering of arterial pressure occurs. Such a combination of events would prevent the

signs, symptoms and physiologic consequences of collapse that otherwise might ensue. Thus, these drugs, unlike the peripherally acting vasodilators, seem to maintain the patient in a state of circulatory equilibrium, but with a lower arterial pressure. Whether or not these explanations are correct, the fact remains that both of these long-acting, orally effective drugs in therapeutic doses are capable of lowering arterial pressure in certain hypertensive patients without compromising the circulation in the major organs so far studied. This fact supports the presumption that satisfactory medicinal agents will eventually be found to lower hypertensive arterial pressure physiologically and without untoward side effects.

SUMMARY

Detailed laboratory studies of the physiologic effects of *veratrum viride* and of dihydroergocornine reveal both to be capable of lowering the arterial pressure of certain hypertensive patients without reducing, except initially, the cardiac output or the blood flow through the kidneys, liver or extremities as measured in the resting horizontal position. The nature and mode of action of each of the drugs are discussed.

NOTE.—Since this paper was presented, further studies in this laboratory (Moister, F. C., Stanton, J. R., and Freis, E. D.: Observations on the Development of Tolerance During Prolonged Oral Administration of Dihydroergocornine, *J. Pharmacol. & Exper. Therap.*, to be published) have shown that patients become resistant to the hypotensive and sympatholytic actions of dihydroergocornine after long-continued oral administration.

ABSTRACT OF DISCUSSION

DR. HANS H. HECHT, Salt Lake City: With the presentation by Dr. Wilkins and his co-workers, another sympatholytic compound has come into its own. I should like to stress briefly the relationships and differences of various agents recently introduced that are supposed to perform, or that is hoped some day will perform, what might be termed a chemical sympathectomy. None has really been demonstrated to do just that as yet. They all have different sites of action. The first compound that received general attention was the tetraethylammonium ion. Tetraethylammonium simply blocks autonomic ganglions and, therefore, causes a number of effects over and in addition to its sympatholytic properties. For instance, with tetraethylammonium one can temporarily shorten an abnormally prolonged auriculoventricular conduction (PR interval). It is a drug that has a wide range of action. The next agent that has been used for some time, but only recently more extensively in this country, is prisol® (2-benzyl-4,5-imidazole hydrochloride), structurally similar to privine® hydrochloride (naphazoline hydrochloride), a vasoconstrictor. Prisol® is an ordinary peripherally acting vasodilator, but, as Dr. Hendrix has shown, it becomes truly sympatholytic in large doses. The two effects are not easily separated. A third compound is called dibenamine® (N,N-dibenzyl-beta-chloroethylamine). It is a nitrogen-mustard derivative which was developed during the war and, in contrast to all the other agents, is specifically directed toward blocking only the excitatory effect of epinephrine at the peripheral muscle. It has a small focus of action, which is of value, and, again in contrast with other compounds, it asserts a prolonged action, which is measured in days rather than in minutes. Dihydroergocornine appears as an important new development. Ergotamine has been used in animal experiments for a long time to block the sympathetic system, but dihydroergocornine as now developed has a pronounced and more specific sympatholytic effect. Ergotamine is also a local vasoconstrictive agent. I am grateful to Dr. Wilkins and his co-workers for their presentation. Before long, chemical sympathectomy will have been presented, but, supposing that an agent which performs a chemical sympathectomy is discovered, the problem

17. Freis,^{1a} Wilkins, R. W.; Culbertson, J. W., and Halperin, M. H.: The Hemodynamic Effects of Sympathectomy in Essential Hypertension, *Ann. Int. Med.* 30: 291, 1949.

of Raynaud's syndrome, the problem of peripheral vasospasm and, above all, the problem of the hypertensive syndrome will still not have been solved.

DR. S. K. ROBINSON, Chicago: I have been coming to these meetings on hypertension for about fifteen years, and I think that progress is now being made, especially after hearing the presentation by Dr. Wilkins and his co-workers. A good many of you undoubtedly heard Dr. Wakerlin's presentation. I want to repeat a statement he made: "Ninety per cent of essential hypertension is of nonrenal origin." That is of tremendous importance. As long as one has the idea that a primary disease like hypertension can be produced by a vegetative organ like the kidney, there will not be much progress in hypertension. The next differentiation I would like to make is between high blood pressure and hypertension. High blood pressure can be produced by the injection of various substances, or by ligation of the renal artery and is not the same disease as occurs in human beings. The experimenters have produced high blood pressure. Hypertension is not entirely a question of hemodynamics; it may involve distant organs and systems. When the hypertensive patient comes to the doctor he may complain of dizziness, dyspnea, fatigue, and, according to certain workers, these symptoms can be resolved by psychotherapy. Other symptoms and signs may be edema, high basal metabolic rate—and let me say here that no examination of the hypertensive patient is complete without a basal metabolism test—impending cardiac failure, anemia and diabetes. First and foremost in therapy is weight reduction. The rice diet contains only about 20 Gm. of protein, and one cannot keep a patient on that diet very long without injury to the liver. Shemm's diet for edema, with the water thrust, is very effective. The elevated pulse rate responds, according to Bram, to treatment with neostigmine bromide. It is necessary that one discover hypertension early, before the patient comes to the doctor with blood pressure of 200 or so. By the routine measuring of the blood pressure the hypertensive patient with a blood pressure of 160 or so can be discovered. The early conditions respond better. There are two syndromes that are frequently associated with hypertension: the gastrocardiac syndrome and the so-called hyperthyroid hypertension. In treatment of the former, the avoidance of gassy foods is helpful. In hyperthyroid hypertension the elevated basal metabolic rate is more easily reduced than the hypertension; useful aids are vitamin A in large doses and, as mentioned before, neostigmine bromide, and propyl thiouracil. When all methods fail, the use of roentgen rays to the sympathetic chain and the pituitary may give good results.

DR. SIBLEY W. HOOBLER, Ann Arbor, Mich.: Since other sympatholytic drugs have been discussed, it might be interesting to summarize similar studies with the autonomic blocking agent, tetraethylammonium. As a rule the reduction in blood pressure with this drug is not the result of a decrease in cardiac output as measured in the human subject by the direct Fick or ballistocardiographic technics. The renal blood flow is well maintained despite the decline in blood pressure, thus suggesting a certain degree of vasodilatation. There is an increase in peripheral blood flow as measured in the plethysmograph, despite the fall in blood pressure. My co-workers and I also studied the effect of tetraethylammonium on the splanchnic blood flow in the manner described by Dr. Wilkins and his co-workers, and were unable to demonstrate significant vasodilatation in this vascular bed. These observations with various sympatholytic agents demonstrate that sympathetic vasoconstrictor tone plays an important role in the maintenance of the increased peripheral resistance in hypertension. The best sympatholytic drug has not yet been found, but the observations of Dr. Wilkins and his co-workers and Dr. Hecht are certainly stimulating to further research in this direction.

DR. ROBERT W. WILKINS, Boston: I wish to thank the discussers for their consideration of this paper. I think that we are all perhaps more aware of the action and possible implications of the sympatholytic drugs than we are of the nonsympatholytic drugs. If I were to give emphasis to either one of these two different classes of agents, if only for the reason that everyone else has emphasized the sympatholytic

drugs, I would call attention again to the possibility of lowering blood pressure with agents that definitely are not sympatholytic. Krayer and Acheson have given an excellent review in *Physiological Reviews* (23: 383, 1946) on the subject of the veratrum alkaloids. Regarding the questions handed me, "Do hypertensive patients differ in their reactions to dihydroergocornine in terms of possible etiologic aspects of the hypertension?" the answer is: not as far as we are able to tell. It is fair to say that only a small proportion of these patients have a satisfactory lowering of their basal arterial pressure with administration of this drug, and so far we have not been able to attribute their responsiveness to any particular underlying mechanism or disease. To the question, "Veratrum viride is an old drug. Are you using a new form?" the answer is: No, we are using the same old drug. We hope to have (and they are becoming available) pure alkaloids of the drug such as those used by Krayer and his group in their pharmacologic studies. They are as yet not available except for experimental work in human beings. The request has been made, "Explain dosage and administration and preparations available. What percentage of patients respond?" Since this is not a clinical presentation but merely a laboratory study, I think that it would be inappropriate at this time to go into the details of the clinical management of patients with these agents. It is still decidedly on an experimental basis, and I would be unwise, without taking a great deal of time, to try to explain how painstakingly one must manage the dosage of the various drugs used.

PERSONALITY FACTORS IN ARTERIAL HYPERTENSION

GREGORY C. GRESSEL, M.D.

FRANK O. SHOBE, M.D.

GEORGE SASLOW, M.D.

PHILIP H. DuBOIS, Ph.D.

and

HENRY A. SCHROEDER, M.D.
St. Louis

Numerous students of this subject have concluded that personality malfunctioning is unusually frequent in hypertensive persons. The general pattern of maladjustment in interpersonal relations (in such persons) has been variously considered to be habitual unexpressed or displaced hostility (Wolfe,¹ Miller,² Rennie,³ Saul,⁴ Alexander,⁵ Weiss⁶ and Binger and his co-workers⁷); lifelong emotional lability with frequent depression, anxiety or both (Rennie,³ Gold⁸); lifelong anxiety, perfectionism, compulsiveness or difficulty with authority (Dunbar,⁹ Binger and his co-workers⁷). The studies have rarely involved more than a few subjects and have rarely included nonhypertensive persons for comparison; hence the comparative frequencies

of occurrence of various possibly relevant personality patterns in hypertensive and nonhypertensive persons are not known.

As part of a comprehensive study of hypertension, we have therefore decided to examine this matter afresh. After careful review of our own and others' experience, we have taken our departure from the following points:

1. The presence or absence of a relevant crisis in the habitual pattern of life of the subject is not likely to be a helpful indicator. Weiss⁶ was not satisfied that he could establish the presence of such crises in more than a few of 93 subjects, but Dunbar⁹ considered that such crises had been detected in 90 per cent of her subjects. Our own experience is like Weiss's: the detection of hypertension need be associated with no crisis that is temporally or otherwise significant.

2. The presence or absence of specific patterns of the earliest childhood conditioning is not likely to be a helpful indicator. Such patterns are exceedingly difficult to establish, and even more difficult to establish as to comparative frequency in a representative sample of hypertensive and nonhypertensive persons. Thus Alexander⁵ reported 1 case; Saul⁴ described 7. "Theoretical" predictions of such frequencies have been based on the prolonged study of a few subjects (Halliday,¹⁰ page 99), in the related field of gastrointestinal psychosomatic disorders, but apparently such predictions are premature generalizations, for they are completely contradicted by a careful study of the same problem by Klein¹¹: few of her group of 100 subjects had had the predicted lifelong preoccupation with the intestinal tract, or diarrhea, constipation or feeding or eating difficulties in childhood. In any case, such specific patterns if present presumably have correlates in the later recurrent patterns of interpersonal relations and of reaction to crisis; these are easier to study and have not yet been studied with respect to comparative frequency of occurrence.

3. It does not seem probable that a specific "personality structure" will be found to distinguish hypertensive subjects from subjects with other accepted "psychosomatic affections" (asthma, ulcer, colitis). Halliday¹⁰ (page 51), who in one place writes as if a specific personality structure (symbolized by "preoccupation with security" or "preoccupation with work," etc.) does correspond to a given psychosomatic disease, contradicts himself in subsequent places (e. g., page 52), pointing out that the same person may have several psychosomatic diseases during his life either simultaneously or in irregular succession and that it is hardly conceivable that his "personality structure" is multiple or changes each time. Careful reading of Halliday's examples of specific personality structures shows that, in persons with psychosomatic diseases, there are: (a) a general pattern of interpersonal relations, involving overinhibition; overconformity; displaced, delayed or inadequate overt emotional expression, and (b) diverse verbal symbolizations of this pattern related to the diverse early verbal conditionings associated with inculcation of the general pattern. That there is such a general pattern in such

persons is our own experience and that of Ludwig.¹² There are other observations of the occurrence of more than one psychosomatic disease in one subject.¹³

4. It seems to us reasonable, therefore, as a first order approximation, to compare the frequencies of certain types of personality functioning in hypertensive persons as a group with the frequencies in two other groups from which the commoner other psychosomatic diseases are excluded (asthma, colitis, rheumatoid arthritis, migraine, ulcer). The inclusion of other psychosomatic disorders in the control population might serve only to blur distinctions indicated by the crude methods with which we must begin.

5. From what has been said, it seems reasonable also to compare the groups in terms of (a) habitual patterns of interpersonal relations or habitual patterns of reaction to crisis, (b) patterns which could be described fairly explicitly and (c) (for purposes of statistical analysis) patterns which show several discriminable degrees of severity of disability.

6. Since patterns of personality disorder (and presumably of habitual personality functioning) differ in frequency in diverse groups that differ in population density of community of origin, dominant stock in the cultural pattern, education, occupation and socioeconomic level, color and sex (for example, Hyde and Kingsley¹⁴), the three groups compared were matched for these or similar characteristics. Individual matching was not feasible. The degree of group matching achieved is shown in table 1.

7. The groups should be matched approximately as to age, since the frequency of hypertension varies with age.

8. There are different types of essential hypertension (neurogenic, endocrine, renal, mixed, etc.).¹⁵ These groups need to be considered separately, before we can be sure that they are homogeneous as to personality functioning.

9. There are different stages of essential hypertension.¹⁶ These need to be considered separately until we can be sure that they are homogeneous as to personality function. The present report does not take adequate account of this variable.

10. It is possible that an unknown number of our nonhypertensive subjects are "prehypertensive." The effectiveness of the cold pressor test in detecting prehypertensive persons is uncertain.¹⁷ Hence, for the present, groups have not been matched so that "hyperreactors" have been identified and excluded from groups II and III (nonhypertensive).

METHOD

About 50 consecutive subjects with essential hypertension were studied (group I). They were referred to us after necessary medical studies had been made and the diagnosis established. The sources of referral

17. Page, I. H., and Corcoran, A. C.: *Arterial Hypertension: Its Diagnosis and Treatment*, Chicago, The Year Book Publishers, Inc., 1946.

were (a) internists on the staff of Washington University School of Medicine, (b) the teaching medical wards of Barnes Hospital and (c) the Hypertension Clinic of the medical school. All necessary medical studies were carried out by the hypertension research group under the direction of one of us (H. A. S.). The patients met the criteria (a) of having sustained blood pressure values exceeding 140 mm. of mercury systolic and 90 mm. of mercury diastolic, (b) of having essential hypertension and (c) (after psychiatric evaluation) of being nonpsychotic.

The composition of group I was tabulated in relation to age, sex, education and other factors. Attempt was then made to match this composition with about 50 subjects (group II) chosen consecutively. In addition to meeting the matching criteria, the subjects in group II (a) had had careful medical study, (b) had had several blood pressures recorded during such study with no readings exceeding 140 systolic and 90 diastolic, (c) had received a diagnosis of psychiatric illness in a clinic for psychosomatic medicine conducted by one of us (G. S.), or in our work with hospital psychiatric referrals or private psychiatric patients (G. S., F. O. S.), (d) were not psychotic and (e) did not have one of the more common accepted psychosomatic disorders (asthma, ulcer, etc.). Many of this group had been studied and treated psychiatrically just before the present investigation began; the necessary data were obtained from their clinic, office and hospital records, wherever, these records were adequate.

In a similar way, we attempted to study about 50 subjects (group III) who, in addition to meeting the matching criteria, (a) had chronic medical or surgical disorder, in which psychologic factors are considered to have low etiologic relevance,¹⁸ and (b) were not psychotic. Sources of referral were medical and surgical services of Barnes Hospital. All of this group were interviewed specifically for this investigation, while they were in the hospital. Their records did not have the necessary data. Comparative composition of the groups, in terms of the matching criteria, is shown in table 1.

The personality ratings of many of the group I subjects had been carried out before work was begun on groups II and III. This occurred as a natural consequence of our having started with the hypertensive subjects, more of whom needed to be studied before we could set up a set of matching criteria, as in table 1, against which prospective members of groups II and III could be judged as suitable for study. About half the ratings were made as group judgments (G. C. G., F. O. S., G. S.); the rest were made by only one of us. During group discussions, only rarely did differences of opinion about a rating exceed one unit on the scale for a given pattern. The data used for rating were obtained in psychiatric interviews. For groups I and II from one to four interviews were used, as a rule; where necessary, more. For group II (patients undergoing or who had undergone psychotherapy), many more interviews were available; we did not notice that there were any significant changes in our ratings depending on our use of the first few interviews or the use of the entire set of interviews. No over-all tabulation of the data was begun until the investigation was nearly completed. The careful classification of the

subjects with hypertension (as to type of hypertension) was carried out with Dr. Schroeder's assistance, toward the end of the investigation.

For the personality ratings, we experimented with a number of habitual patterns of reaction to crisis and of interpersonal relations, of which only the following seemed feasible: hysteria, anxiety, depression, obsessive-compulsive behavior, subnormal assertiveness and impulsiveness. We dropped excessive insecurity, inhibited impulsiveness, precipitating crisis and various others.

* Percentage to nearest whole number.

† For convenience, only these age groups are used in the table. In the computation of coefficients of correlation, age was coded in 11 steps.

‡ More than ten years of early life in a community of less than 2,500 population.

§ One to ten years of incidental residence in a rural area, but not on an operating farm.

¶ Never lived on a farm or in a rural area.

† Occupational class (listing modified from Kinsey and his co-workers [Kinsey, A. C.; Pomeroy, W. B., and Martin, C. E.: *Sexual Behavior in the Human Male*, Philadelphia, W. B. Saunders Company, 1948, pp. 77-78]): 0, dependent, if adult other than a spouse, and completely dependent; 1, day labor and semi-skilled labor; 2, skilled labor, lower and upper white collar group; 3, professional group, business executives, the extremely wealthy; 4, a minor or spouse dependent upon supporting adult of class 1; 5, a minor or spouse dependent upon supporting adult of class 2; 6, a minor or spouse dependent upon supporting adult of class 3.

The patterns were rated on the scale 0, 1, 2, 3 and 4. Samples of the definitions of the pattern at the different rating levels follow.

Impulsiveness

- 0: Very infrequently acts on impulse, and only in minor matters.
- 1: More impulsive than average of his fellows; lifelong pattern. Gets on fairly well. Infrequent outbursts with consequent loss of spouse, friends, jobs.
- 2: Regularly has difficulty with spouse, subordinates, co-workers, superiors, because of impulsive actions. Rare anti-social actions (e.g., stealing, sexual deviations), but in general manages to stay within social bounds.
- 3: Lifelong history of impulsive actions, with severe childhood conflicts with authority, some police experience, frequent change of sex partner or of job or similar actions. No remorse. Considered not desirable by most in the community.

18. Examples of the disorders present in subjects of group III are: bronchiectasis, cystic disease of the lung, Hodgkin's disease, hypoplastic anemia, sickle cell anemia, cirrhosis (nonalcoholic), lymphoma, pernicious anemia, Addison's disease, chronic otitis media and carcinoma.

- 4: Lifelong antisocial behavior, with no remorse. Frequent and severe difficulty with the law (stealing, sex "crimes," homicide); chronic alcoholism; behavior compatible with that of primary or secondary psychopathic personality.¹⁹

Subnormal Assertiveness²⁰

- 0: Regularly expresses his views, differences and dislikes in nearly all interpersonal relations; occasional antagonism provoked by him.
- 1: Shows appropriate assertiveness regularly in at least one major area of interpersonal relations (family, work, school, church, army, etc.); but as a rule in most other areas experiences impulses to differ, to be hostile, without appropriate overt activity; can easily verbalize the felt resentment, anger or disappointment at such times.
- 2: Rarely shows overt assertiveness; when he does, experiences distress (anxiety, guilt), tends to overshoot the mark and subsequently withdraws to habitual pattern or for a time becomes excessively ingratiating, submissive, apologetic.
- 3: Has hardly ever shown overt assertiveness since childhood; is aware of feelings of anger or hostility, but has difficulty verbalizing these even to physician.
- 4: Practically never shows overt assertiveness, denies any awareness of hostile feelings or attitudes, but makes excuses for persons who misuse him (as authority figures).

Obsessive-Compulsive Behavior

- 0: No history elicited of habitual or recurrently episodic meticulousness, overconscientiousness, ruminative thinking, repetitive acting, ritualistic behavior.
- 1: Habitual or recurrently episodic meticulousness and the like (as in 0), which do not decrease subject's general effectiveness and do not produce symptoms.
- 2: Habitual or recurrently episodic meticulousness and the like, with noticeable associated decrease in general effectiveness or associated presence of symptoms. The repetitive patterns can be interrupted without production of great anxiety.
- 3: Well established repetitive thinking, acting, with obvious disorganization or anxiety symptoms resulting directly from interruption of the patterns.
- 4: Disabling obsessive-compulsive neurosis, as hand-washing neurosis, with inability to carry on life pattern like that of subject's peers.

Depressive Behavior

- 0: Very infrequent sadness, in relation to habitual mood.
- 1: Mild but definite episodic sadness or reduced activity level ("sad," "blue," "down in the dumps"). Decrease in social life, slight changes in sleep pattern or in appetite. Changes not obvious to casual friends.
- 2: Pronounced changes in appetite, sleep, energy level, social activity, self esteem, outlook for the future, mood, ability to concentrate. May be much crying. Occasional suicide ideas, no serious attempts. Able to sustain major obligations (work, family), but with decreased efficiency. Changes noticeable to casual lay observer.
- 3: Changes severer than in 2. Except in special circumstances, unable to sustain major obligations. Decided reduction of interaction with people. Maintains contact with reality.
- 4: Psychotic depression: maximal withdrawal from interactional activity. Little speech. May need to be fed.

19. Karpman, B.: *The Myth of the Psychopathic Personality*, Am. J. Psychiat. 104: 523, 1948.

20. We have used this relatively impersonal term to connote a group of phenomena having to do with the subject's "trend toward increased autonomy" (Angyal, A.: *Foundations for a Science of Personality*, New York, Oxford University Press, 1941): spontaneity, initiative, aggressiveness, difference, anger, hostility and hatred and their overt expression. The ratings emphasize the facts that so many of our subjects have decided inability to show overt expression of impulse that is appropriately graded, directed and timed and that they live in a state of habitual recurrent blocking of impulses to act, punctuated by covert or overt explosions of dysfunction.

Anxiety

- 0: Anxiety symptoms (heart pounding, sweating, fear, over-breathing, blurred vision) only in close temporal relation to a severe ongoing disruption of the habitual pattern of life (crisis), e. g., bereavement, loss of job, loss of career.
- 1: Anxiety symptoms in close temporal relation to ongoing moderately severe crisis, e. g., jilting in a casual affair, definite but not serious fall in scholastic standing, subject's child ill with influenza. Symptoms appear excessive in duration and intensity, in relation to the crisis as met by similar subjects.
- 2: Frequent anxiety symptoms; in relation to recurrent ordinary hazards, difficulties, frustrations, memories of unhappy events, anticipations of anniversaries of unhappy events. Symptoms soon cease when stimulus ceases; source of symptoms fairly easily demonstrated.
- 3: As in 2, but with anxiety symptoms of much longer duration after being set up; relationship to evoking situation not easily demonstrated; definite free periods between anxiety episodes still exist.
- 4: Constant chronic anxiety state.

Hysteria²¹

- 0: Very infrequent hysterical symptoms.
- 1: Five to ten episodes of hysterical symptoms, intermittent, with long free periods. Subject never considered the symptoms a serious illness.
- 2: Lifelong history of frequent episodes of vague illness, with complete recovery despite absence of definitive diagnosis or of specific treatment; chronic complaints involving more than one of the types of dysfunctions listed.²¹ Not more than one episode of invalidism or hospitalization for such dysfunctions.
- 3: Never healthy; many episodes of severely disabling illness involving several types of dysfunctions, but with no definitive "organic" diagnosis established or even likely. Usually there have been several surgical procedures, long periods of invalidism or hospitalizations for study.
- 4: Complete continuous invalidism with history as in 3; conspicuous "belle indifférence"; disabling phobias; pseudo-psychotic symptoms.

RESULTS

Group I has been subdivided into two groups: Ia (neurogenic hypertension) and Ib (other types of hypertension). Table 2 shows the number of subjects in group Ia, group Ib and group I (Ia plus Ib) who were assigned ratings of 0, 1, 2, 3 or 4 for each of the personality patterns considered.

It should be noted that the patterns rated have little to do with either the age at detection of hypertension or the duration of hypertension; with few exceptions, the patterns defined were present at the rated levels long before the detection of hypertension.

We have tested the hypotheses that differences between groups Ia and Ib exist in each of the patterns rated. For a difference to be considered statistically significant at the 5 per cent level, the critical ratio (C. R.), or difference between the means of the ratings for a given pattern, divided by the standard error of that difference should exceed 2.45. In no case was the critical ratio greater than 1.29. Hence no significant difference between the two subgroups of hypertensive subjects is apparent for any of the patterns rated. This is a completely unexpected result, in that nearly half (11 of 26) of the "other types of hypertension" were endocrine, in relation to pregnancy.

21. In the absence of a generally accepted definition of the term, we have taken it to mean a *lifelong disorder, characterized by multiple transient dysfunctions* (motor, sensory, autonomic, emotional, intellectual, social, pseudoneurologic, pseudopsychotic), most of which are easily identified (on study) as consequent on definable changes in the life situation.

Table 3 shows the means of the ratings for each pattern in the two subgroups, the difference between the means for each pattern and the critical ratio of each difference.

From this point on, groups Ia and Ib will no longer be considered separately, but will be lumped together as group I, for purposes of subsequent comparisons.

Table 4 shows the number of subjects in group II (personality disorder without hypertension) and group III (chronic somatic disorder) who were assigned ratings of 0, 1, 2, 3 or 4 for each of the personality patterns considered.

In order to test the degree of association between each of the rated patterns in group I, II and III and

the presence or absence of hypertension, point biserial coefficients of correlation were computed. The point biserial is an algebraic variant of the ordinary Pearsonian coefficient of correlation. It is used to indicate the degree of association between a continuous variable and a dichotomous variable, when no assumption is made as to the normality of the distributions. In computing the coefficients, the presence of hypertension was arbitrarily assigned the numerical value of one and absence of hypertension was assigned the value 0. Consequently, positive coefficients indicate a higher mean rating of a pattern for the hypertensive subjects, while negative coefficients indicate the reverse. In the same way, the presence of personality disorder was assigned the numerical value 1 and absence of personality disorder the value 0.

To test the significance of these correlations, we have used the standard error of a zero coefficient of

correlation ($r = 0.0$), which, for these samples, is 0.10. A correlation coefficient (in table 5) greater than 0.30 would be considered to indicate a statistically significant degree of association.

Table 5 shows the point biserial coefficients of correlation between hypertension and absence of hypertension

on the one hand and personality ratings on the other, for (a) groups I and II and (b) groups I and III (columns A and B).

In groups II and III there is no hypertension. As has been stated, group II patients are psychiatrically ill and group III patients have chronic somatic illness, without personality disorder. For these patients the correlations were computed between personality disorder and absence of personality disorder as the dichotomous variable and personality ratings as the other variable; these correlation coefficients are shown in column C.

The ratings of obsessive-compulsive behavior and of subnormal assertiveness differentiate significantly

hypertensive persons from those having personality disorders without hypertension; the other ratings (hysteria, anxiety, depression, impulsiveness) do not so differentiate. The ratings of all the patterns except impulsiveness differentiate significantly hypertensive persons from those with chronic somatic disorders.

As between the two groups of patients without hypertension, namely, those with personality disorders (group

II) and those with chronic somatic disorders (group III), four patterns were found to differentiate significantly: hysteria, anxiety, depression and subnormal assertiveness. Two patterns, obsessive-compulsive behavior and impulsiveness, do not differentiate these two groups significantly.

Fig. 1.—Relation of presence of hypertension to ratings of six personality patterns (50 patients with hypertension and 49 with personality disorders without hypertension). The vertical column of figures on the left shows the percentage of hypertensive subjects.

As has been stated, in differentiating the hypertensive persons from those with personality disorders without hypertension, the patterns that are most differentiating are obsessive-compulsive behavior ($r = 0.44$) and subnormal assertiveness ($r = 0.38$). The correlation coefficient between these two variables is 0.49, which shows that these two rated patterns have a considerable degree of communality. Nevertheless, the multiple correlation coefficient between hypertension and absence of hypertension and these two patterns considered in combination is 0.49, which indicates that combinations of the rated patterns may be found which may be more differentiating than any one pattern in isolation.

The best combination of patterns for differentiating group I (hypertensive) and group III (chronic somatic disorders) appears to be depression and subnormal

While the possibility of using the multiple correlation technic for increasing the differentiating power of the rated patterns has not been fully explored, the inter-correlations among the patterns are such that no great increase is to be expected. This, however, is a subject for further investigation.

Since it was impossible to match the three groups perfectly for age (table 1), the variability associated with age was held constant by means of the partial correlation technic for those patterns significantly associated with hypertension. While the corresponding coefficients of correlation dropped slightly when age was partialled out, the greatest decrease was from 0.44 to 0.40 for the correlation between obsessive-compulsive behavior and hypertension. In no case was a correlation coefficient decreased to a significant degree. In our data, therefore, the relationship between the ratings and hypertension cannot be attributed to age.

In figures 1, 2 and 3 are represented graphically the data which have been described in statistical terms in table 5. The ratings were grouped in the classes 0, 1 and 2, and 3 and 4, in order to provide as large samples as possible over the extent of the rating scale; but the statistical analysis indicates that the general

Fig. 2.—Relation of presence of hypertension to ratings of six personality patterns (50 patients with hypertension and 44 with chronic somatic disorders). The vertical column of figures on the left shows the percentage of personality disorders.

facts shown graphically would be the same, no matter how the ratings were grouped. The graphs were made up as follows (fig. 1, left corner): 27 subjects from groups I and II were rated 3 or 4 for the pattern hysteria. Of these 27, 13, or 48 per cent were hypertensive (group I). Twenty-seven subjects from groups I and II were rated 1 or 2 for the pattern hysteria. Of these 27, 14, or 52 per cent, were hypertensive. Forty-five subjects from these two groups were rated 0 for the pattern hysteria; of these 45, 23, or 51 per cent, were hypertensive.

Thus approximately 50 per cent of the subjects in groups I and II who were rated at any level of the pattern hysteria were hypertensive; the rest were not. This amounts to saying that the rating for the pattern hysteria does not differentiate significantly the hypertensive subjects from those with personality disorders without hypertension; a conclusion put more concisely in table 5, where the relevant coefficient of correlation is shown to be -0.04 , which is not significant.

What has been said of hysteria applies to anxiety, depression and impulsiveness, but not to obsessive-compulsive behavior or to subnormal assertiveness, for groups I and II (fig. 1).

Figures 2 and 3 are to be interpreted similarly: The necessary data for the three figures are in tables 2 and 4.

Fig. 3.—Relation of presence of hypertension to ratings of six personality patterns (50 patients with hypertension and 44 with chronic somatic disorders). The vertical column of figures on the left shows the percentage of hypertensive patients.

assertiveness, which yield a multiple correlation coefficient of 0.69. Approximately the same multiple is yielded by the combination of anxiety and subnormal assertiveness. However, these multiples are only 0.02 higher than the zero-order correlation coefficient of 0.67 between subnormal assertiveness and hypertension.

COMMENT

The significant association of hypertension with obsessive-compulsive behavior and subnormal assertiveness is in agreement with Halliday's¹⁰ (page 52) general experience, and many of our observations are in general agreement with those of Binger and his co-workers.⁷

The latter report indicates that one or both of these patterns were present to a handicapping extent in 22 of the 24 hypertensive subjects studied. Nineteen of their subjects had conspicuous difficulty in asserting themselves, but only 3 are described as obsessional. Decided inability to grade assertiveness, severe degree of anxiety, depression and hysteria are noted also in a fair percentage of their subjects.

Additional rough checks on the adequacy of our method are indicated by the facts that (a) the complex patterns rated, though highly intercorrelated, discriminated effectively the three rather different groups studied, (b) a pattern found relatively infrequently among adults in our society, "impulsiveness," occurred in the three groups with a uniformly low frequency and (c) the ratings differentiate between hypertension and somatic disorders and between personality disorders and somatic disorders more effectively than between hypertension and personality disorders. Only two of the personality ratings differentiate significantly between groups I and II, while five of the ratings do so between groups I and III and four do so between groups II and III. Furthermore, the significant point biserial coefficients are highest between groups I and III, next highest between groups II and III and lowest between I and II. The cited facts are evidence that hypertensive persons resemble those with personality disorders much more closely than they resemble persons with somatic disorders, as has recently been the general psychiatric supposition and the experience of Halliday¹⁰ (pages 54 and 55).

A surprising observation is the absence of significant differences in the ratings for neurogenic and for other types of hypertension (endocrine, renal, mixed). The report of Binger and his co-workers⁷ also indicates great similarity in the personality patterns of subjects with various types of hypertension.

It should be emphasized that the described positive associations between presence of hypertension and certain personality ratings do not signify an etiologic relation between the significant patterns and hypertension, but only that there is concomitant variation of the two variables. What could be the nature of such an etiologic relation? How could it be established more surely? We might postulate (a) that persons with the implied makeup of hypertensive persons are recurrently and frequently inhibiting impulses to overt action, (b) that blood pressure rises occur in some of these persons at such times, just as other dysfunctions obviously occur at such times, (c) that in time, and in some such persons, the blood pressure rises begin to outlast the duration of inhibited impulse and (d) that finally hypertension is sustained instead of intermittent. Such postulates would be compatible with (1) the habitual nature of the personality patterns in question, (2) the frequent observation of a period of lability of blood pressure antedating sustained hypertension, (3) the high correlation between even transient elevations of systolic pressure and later sustained hypertension with its complications,²² (4) evi-

dence suggesting that other factors play a partial causative role: somatic, genetic (Ayman,²³ Friedman and Kasanin²⁴); racial-cultural (the existence of anxiety-ridden cultures in which hypertension is not mentioned)²⁵ and (5) experimental evidence that subjection of mammals to recurrent mutually exclusive drives (i. e., to recurrent inhibition of impulses to overt activity) may bring about not only general disorganization²⁶ but, in particular circumstances, sustained hypertension.²⁷

Such postulates could be tested by observations of the effect on the hypertension of demonstrated modifications of the significant personality patterns; by careful studies of the behavioral (operational) correlates of supposedly identical "anxiety" in different cultures (perhaps these correlates are widely different); by careful studies of the association between change in prevalence of hypertension and change in personality patterns in a cultural group (with hitherto low prevalence) that is undergoing rapid acculturation²⁸ and by still other methods independent of the present one.

SUMMARY AND CONCLUSIONS

The degree of association between presence of hypertension and certain personality patterns has been studied, in (a) hypertensive persons and (b) two control groups. Statistically significant degrees of association are found for "obsessive-compulsive behavior" ($r=0.44$ plus or minus 0.10) and for "subnormal assertiveness" ($r=0.38$ plus or minus 0.10). This association implies concomitant variation, rather than proves etiologic relationship.

Neurogenic hypertensive and other types of hypertensive subjects have not been shown to differ significantly in the rated patterns. The method described appears to afford a means of objectifying complex relationships suggested by much more laborious study of far fewer subjects and should prove useful in similar investigations.

ABSTRACT OF DISCUSSION

DR. FRANZ ALEXANDER, Chicago: The inability of self assertion, the propensity to yield in arguments and dissensions is an overt and conspicuous feature of the hypertensive patient which can be easily observed in the patient's manifest behavior. That this chronic state of inhibition under the surface produces a state of emotional tension which can be compared with an overheated steam engine or a rumbling volcano requires a deeper penetration into the more hidden layers of the personality; and that this inhibition to express aggressive and self-assertive impulses is based on the patient's emotional dependence on others whose good will the patient desperately tries to preserve can be ascertained only by a still deeper study of the emotional dynamics. Only after these emotional connections between dependent needs and inhibition of aggressive impulses are understood is it possible to test the validity of these concepts by a statistical study of larger groups. This is what Dr. Saslow attempted by a thorough psychiatric examination of hypertensive patients and control groups. The statis-

tically meaningful frequency of inhibited personality among hypertensive persons was to be expected on the basis of clinical studies by my co-workers and me. The frequency of compulsion-neurotic traits is interesting but does not constitute an independent fact. It can be well explained from the basic observation that these patients have difficulty in handling their aggressive impulses. The compulsive traits represent precisely an attempt to allay anxiety which develops as a reaction to excessive hostile destructive impulses. By the exaggerated observance of social standards of cleanliness and punctuality, these patients try to placate their guilty conscience, just as little children try to placate their mothers by being very, very good. The important issue is that this guilty conscience is reaction to excessive hostile impulses. I should like to mention the interesting observation which is also confirmed by the statistical observations of Dr. Saslow that a fully developed compulsion neurosis with elaborate system of rituals is rare among hypertensive persons. It has been also noted that essential hypertension may disappear in giving way to the development of a full fledged compulsion neurosis. All this amounts to the fact that by compulsive symptoms the patients succeed in draining their hostile impulses, so that the latter do not produce an increase of blood pressure any more. On the other hand, moderate compulsive character traits, such as overpunctuality, meticulousness, overconscientiousness, are common among inhibited persons. There is a causal relationship between a chronic state of inhibited aggressiveness and a chronic state of elevated blood pressure. It is obviously one of the causative factors. Psychotherapy in many cases succeeds in reducing the blood pressure level. It must be emphasized that only understanding of the totality of the psychodynamic structure which is characteristic of these patients makes statistical observations meaningful. Without such an understanding, derived from detailed psychodynamic studies, intelligent statistical studies are impossible. While Dr. Saslow's work is a welcome validation of formulations derived from psychoanalytic studies, it does not contribute anything essentially new to already existing knowledge. In our complex field, however, such statistical corroboration of dynamic formulations cannot be considered as superfluous.

DR. WALTER BAUER, Boston: A question has been sent to the platform by Dr. Campbell of Los Angeles: "Does the essayist know of any series of cases of hypertension which have had prolonged remissions from psychotherapy alone?"

DR. GEORGE SASLOW, St. Louis: Concerning any demonstrated effect of psychotherapy on hypertension, we require studies which show significant correlations between (a) objectively describable modifications, during psychotherapy, of relevant definable personality factors and (b) sustained reduction of hypertensive blood pressures. Each interested psychotherapist has some hypertensive patients treated only psychiatrically. Of these, some are subsequently normotensive for several years. Such observations are not a systematic study. I know of no published systematic study, nor will such a study be undertaken until less laborious methods of defining personality functioning are devised. Our initial research is exploratory: Can such methods be devised? If the crude beginnings have relevance, they can be refined. When subtle enough, they can be used in a psychotherapy experiment. I should like to thank Dr. Alexander particularly for his agreement that the conception of a personality constellation specific to each psychosomatic disorder has no sound foundation. Present evidence from animal experiments indicates that repeated subjection of rats to two mutually exclusive impulses to act (going for food, being stopped by an air blast), i.e., to recurrent inhibition of an impulse to overt action, can result in sustained hypertension. Our hypothesis is that, in personalities such as we described, the recurrent blocking of impulses to act is associated (in some persons) with transient rises in blood pressure, and in others with colonic spasm, bronchospasm or the like. Further, Paul White has demonstrated a strikingly high correlation between even transient rises in systolic pressure and later sustained hypertension (without, or with, its various complications). Our guess is then that the personality patterns we found significant are a large factor in hypertension. It is unlikely that they

are the sole factor, because (a) the correlations are not high enough, (b) Dr. Page's somatic factors are relevant, (c) genetic factors are apparently relevant and (d) cultures are known which appear to be as anxiety ridden and impulse inhibiting as ours, but from which hypertension is not reported. We suggest that hypertension be studied pluralistically. Remedies may then be found in unexpected quarters, as with typhoid. There treatment of the distant water supply of a potential patient was found more effective than treatment of the patient; also inoculation was found more effective. Maybe the discovery we shall make about hypertension is that it is treated best by treating the social-cultural organization which conditions individual personality patterns.

USE OF A SYMPATHOLYTIC DRUG (PRISCOL®)

From the Point of View of a General Surgical Practitioner

MAX P. ROGERS, M.D.
High Point, N. C.

During the past few years, interest in and investigation of the sympathetic nervous system has rivaled that of the field of antibiotics. Much has been done and written concerning the physiology and pharmacology of alteration in sympathetic function, either by surgical procedure or by drugs.

However, most of the work previously reported has come from large hospital centers where facilities for investigational work and where routines of treatment can be easily established. The time has come, though, where the practical widespread use of these methods must be determined, since the manufacturers of various sympatholytic agents are making them available commercially. The medical profession has asked the question often as to how these agents might be used in everyday practice and which of the agents can be dispensed in the usual office or hospital practice with safety.

The ideal sympatholytic agent, from the point of view of the general medical or surgical practitioner, is that one which can be used intramuscularly, intravenously or orally, so that treatment might be rendered whatever the circumstances might be. Currently, three drugs are under investigation in regard to their properties of sympatholysis. Etamon® (tetraethylammonium chloride or bromide) and dibenamine® (dibenzyl beta-chloroethylamine hydrochloride) both have the ability to block effector sympathetic pathways, but they both have the drawback that they must be administered either intravenously or intramuscularly. This is a definite disadvantage when one desires to treat an ambulatory patient. In 1939, Hartmann and Isler first reported on the third drug of the group, priscol® (2-benzyl-4, 5-imidazoline hydrochloride). This drug has the advantage that it can be given orally as well as parenterally and, therefore, is of greater value as a method of ambulatory treatment. Priscol®, then, was chosen for this study, to determine its usefulness to the general medical or surgical practitioner.

Experiments on the effect or action of priscol®, as well as clinical investigation, have been rather extensive. For this paper, ninety-nine articles were reviewed, but only a few of these will be mentioned. Hartmann and Isler found that the phenyl-substituted alkyl imidazolines are depressors of blood pressure, and priscol® is

Ida M. Sykes and Ruby Dellinger assisted in this study. Priscol® (since this paper was written, the name priscol® has been changed to priscoline®) used in this study was furnished by the Ciba Pharmaceutical Products, Inc., Summit, N. J.

the strongest of them.¹ Meier and Mueller stated that the effect of priscol® is characterized by a dilatation of the vessels of the skin and mucosa and that it increases the vascularization of certain regions, the extremities more than others.² Later, Meier and Meyer, working on the peripheral point of attack of priscol® on the vascular system, stated that no cholinergic mechanism is involved in the priscol® action and that, if the site of action is not the central nervous system, priscol® must act on the adrenergic or sympathetico-mimetic system.³ They also stated that administration of atropine in a dose which definitely inhibits the acetylcholine effect has no influence on dilatations produced by priscol®. (There is some question, however, about priscol's® actually having a cholinergic action, because of the appearance of "goose flesh" in some patients taking priscol®. This occurrence is probably effected by stimulating cholinergic pathways in the sympathetic nervous system.)

Braun, working on vasoconstriction in the tail of a rat, stated that ergotamine, as well as epinephrine, caused damage and that priscol® acted antagonistically toward both of these substances.⁴ Bertazzi and de Gennaro showed that priscol®, in doses of 10 to 20 mg., has a definite stimulating effect in gastric motility, manifested not only by improvement in tone and peristalsis but also in quicker gastric evacuation.⁵ Butturini, in 1940, described the reversal of epinephrine effect on priscol®.⁶ Mueller also proved that priscol® has a definite adrenergic effect.⁷ Frieb, in an interesting article on functional effects of priscol® on various organs, reported that, in elderly persons with hyperglycemia, priscol® produced a normal blood sugar level which would indicate that other drugs which influence favorably the diabetes of elderly persons, but not of younger persons, like testosterone propionate, act not specifically but by improving the vascularization of the tissues. He also reported that priscol® has no effect on the coronary arteries.⁸ (This last observation brings up some question, because priscol® does stimulate the heart rate, and coronary blood flow is increased mechanically along with the heart rate).

Lippross showed that the normal peripheral gradient of the skin temperatures is abolished by priscol®.⁹ Still another report on priscol® and diabetes is that of Carvalho.¹⁰ This showed the blood sugar level of normal or diabetic persons decreased after intravenous or subcutaneous injections of priscol®; the higher the level, the more pronounced the effect, subcutaneous

injections being more effective than intravenous. Kohl-mayer reported that priscol® definitely improved the patient with Raynaud's and Buerger's disease (thromboangiitis obliterans).¹¹ Schnetz and Fluch reported rather extensively on the use of priscol® in angioneurosis, vascular spasms, acrocyanosis, acroparesthesia, frostbite, Raynaud's disease, intermittent claudication, Buerger's disease and arteriosclerotic and diabetic gangrene, with good results.¹² Other good reports with use of the drug in clinical patients were reported by Weitzmann,¹³ Buckreus¹⁴ and Brack.¹⁵

Another interesting report was that of Kutschera-Aichbergen, who reported accidentally, so to speak, that in 2 cases of water retention due to acute or sub-acute nephritis, priscol® produced satisfactory diuresis on intravenous injection.¹⁶ Nespore reported both subjective and objective improvement of hands and face in a case of scleroderma.¹⁷ Later Kutschera-Aichbergen had an additional report on his use of priscol® to combat anuria of nephritis.¹⁸ Also, Coste and Hochfeld, in 1945, reported good results from injections of priscol® in cases of coxitis senilis.¹⁹ (A word of caution should be added that many of these reports deal with only a few patients followed for a short period of time.) Priscol® has also been used in the fields of gastroenterology as a diagnostic and testing agent and also in the fields of ophthalmology and rhinology.

The cases in this report deal with clinical use of priscol® during the eleven months prior to writing. The first patient who was given priscol® had been taking the drug almost continuously during that period of time. All patients were followed with frequently repeated studies of blood and urine, and no significant changes resulted from treatment with priscol®. The material will be presented in three main divisions: (1) observation in the use of the drug in the treatment of peripheral vascular disease, (2) the use of the drug in treatment of hypertension and (3) the use of the drug in conditions not clearly defined. In the earlier days of this work, the dosage schedule was probably too small, as more recently developed schedules of treatment with larger doses have given better results. Testing equipment consisted only of the usual laboratory studies, oscillometric studies with Collin's sphygmo-oscillometer and skin temperature studies with a McKesson dermalor®. Although constant temperature rooms are of a great deal of importance, this was not available and skin temperatures could be taken only in a room with the doors and windows closed after patient had been resting for fifteen to twenty minutes, and then observations were made by comparing the temperature of the skin with the temperature of the room.

Side effects of the drug have been dependent entirely on dosage, and these were well described by Grimson and his co-workers in a complete and exhaustive report in June 1948.²⁰ It has been found that oral doses of 25 mg., every three to four hours, in the majority of cases, produce no side effect whatsoever. Occasionally a patient will state that he feels "squeamish in his stomach" at the beginning of his treatment, but no definite nausea and no vomiting have been encountered. The patient's commonest complaint is probably that of a chilly sensation with development of goose flesh and a sensation of crawling of the skin. Intravenous doses produce a sensation of warmth of the face and arms, crawling of the skin and rarely apprehension. Doses of 25 to 50 mg. of priscol® will seldom produce any significant lowering of blood pressure.

USE OF PRISCOL® IN PERIPHERAL VASCULAR DISEASE

Twenty-seven patients with vascular disease or related disorders of the circulation of the extremities received priscol®. Ten patients had arteriosclerotic peripheral vascular disease, and 3 of these had diabetes. There were 4 cases of Buerger's disease, 6 cases of thrombophlebitis, 3 cases of lymphedema, 1 case of trench foot; 1 case of livedo reticularis and 2 cases of causalgia. In all cases the patients were first tested, with either intravenous or oral doses, and then received oral medication over a period of time.

Arteriosclerotic Peripheral Vascular Disease.—In this group of patients all complained of essentially the same thing, that is, a gradual increase of pain in the legs, particularly in the calves on walking, over a period of time. Of this group, 3 of the patients had arteriosclerosis with hypertension and 4 of the patients had no hypertension. All were above 50 years of age and showed the usual cordlike peripheral arteries in the arms and legs.

The first patient was seen before priscol® was obtained and was treated with Buerger's exercises and later with intermittent venous occlusion. She improved somewhat, and her first oscillometric studies showed a maximum of 2 mm. oscillation bilaterally; these increased to 4 and 5 mm. on intermittent venous occlusion. When priscol® was obtained, her maximum oscillation at the time was 5 mm., and she was first tested with 25 mg. of priscol® intramuscularly. Her oscillometric readings increased to 6.5 mm. She was then given the drug orally, and this was continued for four months. During this period she improved to the extent that she rarely had pain. The patient has had a lumbar sympathectomy on one side and is scheduled for treatment of the opposite side soon. There has been no change in the sympathectomized limb during treatment with priscol®.

The second patient, the brother of a doctor, had not had a great deal of difficulty because of a very sedentary occupation. However, he knew that he could not walk for any distance without pain. Oscillometric studies showed a maximum of 0.5 mm. bilaterally. With priscol®, 25 mg. given orally five times daily, his oscillometric readings increased to 2.5 mm. bilaterally; he can now walk a considerable distance without pain.

Another patient gave a history of gangrene of the toe requiring operation one year prior to being seen. He was seen because of cyanosis and early ulceration of another toe. With priscol® therapy the ulceration cleared, the circulation was reestablished and no amputation has been necessary.

The next patient was seen because of an acute arterial occlusion, superimposed on arteriosclerosis with severe pain and cyanosis of the entire foot. With priscol® therapy the color returned, his pain was relieved and he began to be up and about. However, during the time that he was taking priscol®, another rather extensive arterial occlusion developed and amputation was necessary.

The next patient had been treated for arthritis and rheumatism over a period of a year without improvement and stated that cramps appeared in both calves after she walked one block. She was given priscol®, and during the first week her oscillometric readings increased from 0.5 mm. on the right and 1.5 mm. on the left to 1.5 mm. on the right and 2.5 mm. on the left. She can now walk six to eight blocks without pain.

Another patient was interesting because of associated hypertrophic arthritis of the spine as well as arteriosclerotic peripheral vascular disease with intermittent claudication. With priscol® therapy both the intermittent claudication and the arthritic symptoms improved.

The last patient in this group was seen because of a rather sudden onset of pain in the left foot, which was thought to be an endarteritis superimposed on the arteriosclerotic peripheral vascular disease. Oscillometric readings were 0 in the left leg, and there was a difference of 3 degrees in skin temperature between the right and left great toes. In a test with 25 mg. given intravenously, the pain was relieved, the skin temperature increased, so that there was only 1 degree difference between the right and left foot, and the patient was able to walk without pain.

Arteriosclerotic Peripheral Vascular Disease with Diabetes.—There were 3 patients in this group, and 2 of them were Negro. The first patient, a 59 year old Negro woman, came to the hospital because of a large infected area on the left ankle with cellulitis and early abscess formation. During the early days of her hospital stay the level of her blood sugar was rather high, and after taking priscol® the patient went into insulin shock on several occasions before it was realized that the insulin requirement decreased with this medication. When her insulin dosage was reestablished, while she was receiving priscol® she improved rapidly. The abscess was drained; she no longer complained of pain in her leg and was discharged from the hospital with only a granulating area on the ankle. With continued priscol® therapy, this healed rapidly and the patient has been asymptomatic.

The second patient, a 75 year old Negro man, was also admitted because of an infected ulcer of the foot, diabetes and arteriosclerosis with hypertension. With priscol® therapy the relief of pain was rather dramatic. His diabetes was easily controlled, and the patient was discharged with a small dressing on his foot. About a month later, however, after discontinuing the use of priscol®, this patient had acute myocardial failure and died. The effect of priscol® here, with respect to his heart lesion, is not clearly defined, although it is believed that his demise was due to natural causes of the hypertensive cardiovascular disease.

²⁰ Grimson, K. S.; Reardon, M. J.; Marzoni, F. A., and Hendrix, J. P.: The Effects of Priscol (2-Benzyl-4, 5-Imidazoline HCl) on Peripheral Vascular Diseases, Hypertension and Circulation in Patients, *Ann. Surg.* 127: 968, 1948.

The next patient not only complained of pain in her feet and legs, but also of a great deal of numbness and tingling. With priscol® therapy her diabetes was readily controlled, her pain and numbness disappeared and, as of the time of writing, she had been taking priscol® for approximately two months with no ill effects whatsoever.

Buerger's Disease (Thromboangiitis Obliterans).—There were 4 patients in this group. All of the patients were under 40 and gave a typical history of intermittent claudication with a definite history of a fluctuating course of exacerbations and remissions. They were all seen during an exacerbation and showed diminished pulsations of the dorsalis pedis and the posterior tibial artery with paleness, blanching on elevation and dependent rubor. The first patient was a former army officer who had experienced his difficulty while in the army, where a diagnosis of quadrilateral Buerger's disease was made, and he was sympathectomized bilaterally. He did fairly well for approximately one year, but then began to have recurrence of his symptoms. When he was first seen he could walk only about one block without pain. After two weeks of priscol® therapy, he could walk four to five blocks and oscillometric readings had increased to an average of 2.5 mm. bilaterally. Priscol® therapy was continued for four months and was then stopped, as the patient was apparently in a remission. The improvement with priscol® after sympathectomy affords speculation as to mechanisms involved, but the most plausible assumption is that priscol® was again relieving spasm, which in this instance was apparently due to regeneration of sympathetic fibers.

The second patient, who was only 34, had had trouble with his legs for two or three years. His oscillometric readings were 0 bilaterally, and the patient could walk a distance of only 25 yards (23 meters) without pain. With priscol® therapy he rapidly improved to the extent that he could walk four to five blocks. Priscol® therapy was stopped, and all his symptoms returned; on taking priscol® again he was relieved. He has had a lumbar sympathectomy on one side and will be sympathectomized on the other side. Another patient, age 32, complained of aching and burning pain in both legs of three years' duration, with definite exacerbations and remissions. Oscillometric studies showed a maximum of 1.75 mm. bilaterally. Intermittent claudication occurred after he walked two blocks. With priscol® therapy, 25 mg. four times daily, the oscillometric readings increased to normal and symptoms disappeared. Therapy was continued for two months and then discontinued when the oscillometric readings no longer increased.

The last patient had the onset of his disease at the age of 27, and when he was seen five months later he was almost completely incapacitated. His feet were cold and clammy with absent dorsalis pedis and posterior tibial pulsations and maximum of 3 mm. oscillations bilaterally. Priscol®, 40 mg. given intravenously, abolished the gradient of skin temperatures from the toes to the umbilicus, and his pain disappeared. His walking distance doubled during the first week of therapy.

Thrombophlebitis.—In this group there was a total of 6 patients. Four of the patients were seen in the acute phase with the typical symptoms of fever and

pain. All patients in this group, both acute and chronic, had a positive Homan sign. Priscol® was used in these cases as a substitute for paravertebral sympathetic procaine hydrochloride injections.

In 3 of the cases priscol® was first given intravenously with a prompt reduction of pain within a period of three to five minutes. In the other 3 priscol® was given orally with a decrease in pain within a period of thirty to forty-five minutes. After the initial test doses, priscol® was continued orally, and, as long as priscol® was given in adequate dosage, the Homan sign remained negative and the patients were essentially asymptomatic. In 3 cases it was thought that priscol® influenced the course of the disease, inasmuch as after priscol® therapy was instituted without other change in medication there was a prompt reduction of fever. The 2 cases of chronic thrombophlebitis were of approximately six to twelve months' duration, and improvement was prompt and lasting.

Related Vascular Conditions.—*Trench Foot:* One case was that of a veteran who gave a history of onset of trench foot while in the European Theater of War during 1944. Until the time of his discharge from the armed forces, he was in and out of the hospital frequently with pain, chilling and swelling of both feet. He was discharged with 10 per cent disability in 1946. Examination showed that both feet were cold, clammy and moist. Oscillometric readings were normal, but skin temperatures were low. There was a pronounced dependent rubor, but plantar ischemia was absent. He was given priscol® orally and received it daily, 25 mg. every three hours. This was continued for approximately three weeks. During this period of time he had no pain or swelling, and on discontinuing treatment the patient reported to a national guard camp for a period of two weeks. In spite of his tour of duty there, he still had no pain or swelling.

Livedo Reticularis: The patient was a 27 year old woman who was seen because of mottling of both legs of several years' duration, accompanied with burning pain after standing for any length of time, as well as a significant amount of rest pain. Oscillometric studies showed decreased arterial supply bilaterally with the skin temperature gradient of 26 degrees in the great toe to 31 degrees at the umbilicus. There was plantar ischemia on elevation and dependent rubor with mottling of both legs on dependency. Priscol® given intravenously increased the oscillometric readings by 1.5 mm. bilaterally, and the skin temperature gradient was almost abolished. With priscol® therapy her oscillometric readings became normal. She no longer complained of cold feet. Her mottling was less, and her pain, both while standing and at rest, completely disappeared.

Postphlebotic Lymphedema: Three patients were treated in this group, 2 women and 1 man. The average increase in diameter of the affected leg was 1¼ inches (3 cm.) over the normal leg. With priscol® therapy the edema completely disappeared, and the leg remained normal as long as therapy was continued. In 1 patient there was a recurrence of edema after discontinuation of priscol® therapy. In another there were occasional episodes which could be terminated immediately with priscol®, and in the third case there was complete and permanent disappearance of the lymphedema.

Causalgia: There were 2 patients treated for this dyscrasia. The first was that of a 25 year old veteran who sustained a rupture of the distal end of the right triceps tendon while in the service as a result of a jeep wreck. Since the time of the accident he had had a constant dull aching pain in the arm and shoulder with episodes of acute pain, with tingling, numbness and burning of the index and middle fingers of the right hand. Local physical therapy was of no avail, but priscol®, 25 mg., was administered intravenously during an acute episode. The pain was immediately abolished along with the burning and tingling of the hand. Priscol® therapy was continued for one week orally and then stopped with no recurrence of pain.

The second case was that of a 35 year old woman who complained of pain in the throat, gums and teeth, of approximately eighteen months' duration. She had been seen by a number of nose and throat specialists and dentists without relief. She was in excellent physical condition, and no localized cause for her pain had been found. However, priscol®, 25 mg. given intravenously, abolished the pain. Therapy was continued by mouth, and as long as she continued taking priscol® she had no pain.

HYPERTENSION

In this series 2 patients with hypertension were treated with priscol®. The first was a 53 year old white woman with known hypertension of seven years' duration. She was referred to Duke Hospital for checkup in regard to a sympathectomy. Although it was found that she was an ideal candidate, she did not desire a sympathectomy, and for that reason she was given priscol®. Her blood pressure in the beginning varied from 210 to 240 systolic and from 110 to 120 diastolic. At the time that this report was made she had been taking priscol® almost continuously for eleven months. She was given a regular dose of 50 mg. every two and one-half hours. As of the time of reporting she had a standing pressure of 140 systolic and 80 diastolic.

The second patient was a 41 year old man with hypertension of three years' duration. After his studies were completed in regard to sympathectomy, it was decided to attempt to lower pressure with priscol® before proceeding with surgical treatment. Prior to therapy his blood pressure was found to be 252 systolic and 140 diastolic. With priscol® therapy, 75 mg. every two hours, his standing pressure was 170 systolic and 110 diastolic. This patient had been receiving priscol®, at the time this paper was written, for only about two weeks. In both cases the patient tolerated therapy well and had no complaints whatsoever.

MISCELLANEOUS USE OF PRISCOL®

Tabes Dorsalis.—A 58 year old white man, known to be syphilitic with central nervous system manifestations of several years' duration, had been treated in many places for his central nervous system manifestations. When he was seen he stated that he had tabes. His knee jerks were absent, and his chief complaint when seen was that of "lightning pain" in both legs. The patient admitted that during the past few years he had taken large quantities of "headache remedies" for his pain, as well as morphine and codeine. During cold and rainy weather, he would have attacks of severe lancinating, knifelike pains throughout both

legs. Because of this he was able to work little and was in a great deal of pain most of the time. He was seen during an acute attack, at which time he would sit quietly for a few minutes and then suddenly jump and almost scream because of pain through both legs. Priscol® was given intravenously with immediate relief of his pain. Since taking priscol® orally, he has not required any other pain-relieving medication at all, indicating that his pain was undoubtedly associated chiefly with pronounced vascular spasm.

Syphilitic Gastric Crisis.—A 50 year old man with central nervous system syphilis had received much therapy. He had positive signs of syphilis in the blood and cerebrospinal fluid. During the year prior to examination he had had seven admissions to the hospital because of abdominal pain, nausea and vomiting. A diagnosis of gastric crisis was made, but the patient continued to have many attacks of severe pain, requiring considerable amounts of narcotics for relief. During an acute stage, at which time he had been unable to retain food for approximately four days, it was decided to study the role of vascular spasm in such a case. Priscol® was given intravenously in a dose of 25 mg., with approximately 75 per cent reduction of pain. He then received priscol®, 25 mg., every three hours intramuscularly, and within twenty-four hours he had little pain and no nausea or vomiting. Within forty-eight hours he was eating a regular diet, had no pain and was taking no narcotics. Priscol® was then given orally. He was discharged five days after the start of priscol® therapy, eating well and gaining weight.

SUMMARY AND CONCLUSIONS

To augment the clinical reports of the use of priscol® (2-benzyl-4, 5-imidazoline hydrochloride), the results in 31 cases are presented. It appears that priscol® has a definite place in the armamentarium of drugs in the treatment of many types of conditions, particularly in the field of peripheral vascular disease, or for conditions of visceral pain due to vascular spasm. Presumably this drug can be used to a great advantage in those cases in which sympathectomy would be advantageous, and, if the patient responds to priscol® therapy, the results of a sympathectomy will probably be good. It can also be used as a substitute for paravertebral sympathetic block. Immediate results of the drug can be obtained by its administration intravenously or intramuscularly, and it can then be dispensed in dosages of 25 to 50 mg. every two to four hours as a routine office prescription without danger, in the usual case, with adjustment of the dosage for each patient as necessary. However, priscol® should be used with reservation in patients with known coronary insufficiency or cardiac lesion. Particularly from this point of view, priscol® is of importance to a general medical or surgical practitioner.

The results of the use of priscol® in 2 cases of pain resulting from central nervous system syphilis is unusual and interesting, and, in explanation of its mechanism, it is suggested that in view of the present knowledge of the pharmacologic characteristics of priscol®, the action may be explained on a basis of inhibition of stimuli to the vessels. It is also apparent that in certain cases of causalgia, which are always difficult problems, aid is afforded by treatment with priscol®.

LOCATION OF BRAIN TUMORS BY MEANS OF RADIOACTIVE PHOSPHORUS

B. SELVERSTONE, M.D.

A. K. SOLOMON, Ph.D.

and

W. H. SWEET, M.D.

Boston

Precise location of cerebral tumors at operation has been accomplished by means of a miniature Geiger-Müller counter employed as a probe. With such a purpose in view, one of us (B. S.) suggested, on theoretical grounds, that radioactive phosphorus might concentrate in cerebral tumors. In order to demonstrate the feasibility of this technic, it was essential to prove that radioactive phosphorus would actually concentrate in cerebral tumors to a degree significantly greater than

tumor tissue. The concentration in tumor appeared to increase with increasing cellularity, in tumors of the same group. The maximum concentration ratios were usually reached on the second or third day after injection.

Since approximate location of deep brain tumors has not presented a major problem when neurologic examination, electroencephalography and ventriculography have been carefully employed, we have limited the present study to the more difficult question of precise location. The beta radiation emitted by P^{32} penetrates only about 7.5 mm. in brain or brain tumor, permitting location within this maximum distance.² The miniature counters employed were constructed by Dr. Charles V. Robinson of the Harvard Medical School, who subsequently collaborated with us (figure). They are sensitive only in the terminal 1 to 1.5 cm. Our first counters were 5.0 mm. in diameter, which we now

in normal gray and white matter.¹ Preliminary experiments were carried out in which tracer doses of radioactive phosphorus, as a buffered phosphate solution, were given intravenously to patients with various types of cerebral tumor. Aliquots of tumor removed at intervals after injection of P^{32} were compared for radioactivity with white and with gray matter removed at the same time. The radioactivity of tumor tissue ranged from 5.8 to 110 times greater than that of adjacent normal white matter. The activity of gray matter was ordinarily somewhat greater (about 1 to 2 times) than that of white matter, but never approached that of

consider too large for routine use. At present we use counters 3.0 mm. in diameter, which are of the same size as cannulas customarily employed in ventriculography.³

This report deals with a preliminary group of 14 cases of brain tumor (including glioblastoma, astroblastoma, astrocytoma and atypical glioma) in which the Geiger-Müller probe counter has been employed at operation. In 3 of these cases the tumor was on the exposed surface; in the remaining 11 instances the counter was employed in order to determine the precise location of tumors which were not on the surface. In each instance the patient received intravenously 0.95 to 4.2 millicuries of radioactive phosphorus (as buffered sterile sodium phosphate solution) at intervals ranging from 1.8 to 65.8 hours prior to operation.

Dr. Selverstone is a Senior Fellow in Neurology, The National Research Council.

The United States Atomic Energy Commission gave the radioactive phosphorus used in this investigation.

From the Neurosurgical Service, Department of Surgery, Massachusetts General Hospital, and the Biophysical Laboratory, Harvard Medical School.

The work reported here has been supported in part by the Proctor Fund of Harvard University, Office of Naval Research, National Foundation for Infantile Paralysis, an anonymous grant administered by Dr. J. C. White and an institutional grant of the American Cancer Society.

2. P^{32} gives off only a 1,690,000 electron-volt (1.69 Mev.) beta ray, with a maximum range of approximately 750 mg. per square centimeter in aluminum (Glendenin, L. E.: *Nucleonics* 2: 12, 1948). The counter wall, of copper or stainless steel 0.16 mm. thick, appreciably reduces the 7.5 mm. range. Brain and brain tumor are assumed to have a density of 1.

3. Robinson, C. V., and Peterson, R. E.: *Rev. Scient. Instruments* 19: 911, 1948.

The counting tube is sterilized either by immersion in a formaldehyde base germicide for one hour or by autoclaving at 120 C. for five minutes. The cathode, the only portion in contact with the brain, is at ground potential. A suitable cathode-follower circuit is provided in order to prevent undue loading of the small counting tube by the capacitance of the 10 foot (25 cm.) line leading to the scaler. The appropriate area of cerebrum or cerebellum is then exposed by means of a craniotomy the location of which is based on the usual clinical and laboratory data. A presumed normal control is first obtained by introducing the counter into a convolution in a neurologically "silent" area chosen as far from the probable site of tumor as the exposure will permit. The counter is then decontaminated by irrigation and wiping with a moist sponge, and the background in air is checked. The counter is then successively introduced into suspected convolutions until the tumor is encountered. The presence of tumor is recognized by an immediate increase in counting rate from 5.4 to 36.3 times that encountered in the control area. Before reintroduction, after tumor has been struck, the counter

Miniature Geiger-Müller counter used in locating deep brain tumors.

is cleansed with hydrogen peroxide and alcohol in order to prevent the possible implantation of malignant cells into normal areas. Ordinarily a statistically satisfactory number of counts is obtained within twelve to twenty-four seconds in tumor and within thirty to sixty seconds in normal brain.

Table 1 shows counting rates obtained at comparable depths beneath the surface in normal brain and in tumor. In each instance where a tumor was present, except in case 15 (not shown in the table), it has

TABLE 2.—Counting Rates at Successive Depths with Introduction of Probe Counter Through Brain to Tumor

Case 7		Case 8		Case 10	
Depth, Cm.*	Counts per Minute	Depth, Cm.*	Counts per Minute	Depth, Cm.*	Counts per Minute
2.0	1,278	2.1	1,213	1.5	1,142
4.0	2,168	3.0	1,627	2.2	992
5.0	14,446	3.7	2,885	3.8	650
...		...		4.8	30,077

* In each instance, the gross margin of tumor was identified between the depth of the final and that of the next preceding count, as accurately as we could determine on subsequent direct inspection.

been possible to locate the tumor.⁴ In this case, a deep metastatic nodule, 1.2 cm. in diameter, was never struck by the counter. Autopsy disclosed that the counter had never come closer than 5 mm. to the tumor.

Table 2 shows counting rates at successive depths at the same site of introduction in cases 7, 8 and 10. It will be noted that there is a striking increase in the number of counts when the probe is advanced a final centimeter or less into gross tumor.

⁴ In cases 3, 4 and 11, the location of the tumor was evident on the surface and the counter served merely to verify its presence.

The theoretical and practical limitations of these techniques and the use of the counter in demarcating tumor from normal brain will be discussed in a subsequent detailed communication.

SUMMARY

Radioactive phosphorus injected intravenously appears in human cerebral tumors in high concentration when compared with normal brain. A small probe Geiger-Müller counter has been successfully employed in 14 cases to determine the precise location of deep brain tumors.

RUPTURE OF THE INTERVERTEBRAL DISK

A Short History of Its Evolution as a Syndrome of Importance to the Surgeon

WILLIAM JASON MIXTER, M.D.
Boston

An account of rupture of the intervertebral disk as an important clinical entity must include not only an evaluation of the pertinent literature, but also the experience of my contemporaries and myself.

There is little in the older literature that has not already been noted, and my function, as I see it, is to use the facts contained in it as a background for the important work leading up to present knowledge of the subject. If I have omitted any important contributions to the subject, I trust that such omissions will be drawn to my attention in order that such an error may be corrected in any future publication.

In an interesting old book by Charles Bell,¹ written in 1824, is an illustration which perhaps is one of the earliest drawings of a rupture of the intervertebral disk, though this, like so many other later references, is concealed under the cloak of misconception of the lesion. Bell called it a fracture, and fracture is present. Nevertheless, allowing for a certain amount of error by the artist, I think that one may assume that the lesion depicted might be a gross rupture of the intervertebral disk into the spinal canal without dislocation of one vertebra on another but accompanied with extensive fracture.

For many years thereafter the occasional mention of damage to the disk had to do with rupture or tearing of the disk as part of a gross dislocation, or as the result of wounds, sepsis and the like.

In 1896, Kocher² wrote a long and most scholarly article on the spine and spinal cord and in it gave many case histories. Case 1 is of particular interest. The man fell 100 feet, landing on his feet. He was able to walk, but complained of burning pain in the scrotum and penis and weakness of his legs. He died some hours later apparently from rupture of the jejunum. Autopsy showed that the first lumbar intervertebral disk had been shattered and squeezed out from between the vertebrae into the spinal canal. No mention is made of fracture or of the condition of the cauda equina. This is indeed a milestone in the history of the ruptured intervertebral disk.

In his "Surgery of the Brain and Spinal Cord," Krause³ reported a case of enchondroma of the vertebral column compressing the cauda equina and operated on in 1907. This undoubtedly was a true enchondroma from the description and the drawing. However, in 1909, he, with Oppenheim,⁴ reported another case which is of great importance to us. Their patient, a man, had had attacks of low back pain for years. Shortly before they saw him, he had been in a fight and his back had been injured. Pain in the back and left leg ensued followed by pain in the other leg and gradually increasing paralysis of both legs, bladder and rectum. At operation, a tumor was found and removed. It lay anterior to the anterior dura and apparently was opposite the second lumbar disk. The drawing in their article certainly suggests a ruptured disk. Microscopic examination of the specimen showed it to be composed of sparsely cellular cartilage without evidence of necrosis.

In 1911, Middleton and Teacher⁵ in England and Goldthwait⁶ in this country reported cases of severe injury to the intervertebral disk with transverse lesions of the cauda equina.

Middleton and Teacher's case would seem to be, without question, one of rupture of an intervertebral disk. Their patient, a laboring man, was lifting a heavy metal plate. He felt a sudden sharp pain in his back accompanied with severe pain extending into both legs. Within a few hours, complete paralysis of both legs ensued. He died a few days later. At autopsy, a softening of and hemorrhage about the lumbar enlargement was found and, in addition, a mass of

bral disks was carried out. I suspect that they did not realize that the mass was normal cartilage until later, when the specimen removed was subjected to careful pathologic examination. It is probable that the fragment came from the first or second lumbar disk.

Goldthwait's paper is of interest, as his patient was operated on and the cauda equina explored. His patient had sciatica and paraplegia after sacroiliac manipulation. At operation, the dura was opened and narrowing of the sac at the level of the fifth lumbar disk was noted. No exploration of the anterior epidural space was carried out. This case also would seem to be one of ruptured intervertebral disk, probably the fifth lumbar.

During the next seventeen years, no mention is found of isolated injury of the intervertebral disk as described by Goldthwait and by Middleton and Teacher, but there are reports by Frazier,⁷ Elsberg,⁸ Stookey,⁹ Ott and Adson¹⁰ and others, including myself,¹¹ of "enchondromas" which are now known to have been ruptured disks and not true tumors. During the latter part of this period came the studies of Schmorl¹² and others, and one began hearing of Schmorl's nodules, though I am sure that few if any doctors thought of linking them with the enchondromas. I know I did not.

cartilage lying in the spinal canal. Apparently at the time of the autopsy, the character of this mass was not suspected and no careful exploration of the interverte-

SCIATICA

In this historical sketch a well known painful syndrome, namely, sciatica, must now be considered. The textbooks of neurology and many articles by neurologists and orthopedists testify to the importance of this common malady. Radiculitis, sepsis near or remote, malformations of the transverse processes or the facets, thickening of the ligamentum flavum, sacroiliac disease, tumors of various sorts and various other causes had been discussed, and many of these may cause sciatic pain. Up to 1929, however, little if any attention had been paid to lesions of the intervertebral disk and no one had considered the intervertebral disk to be implicated in any large percentage of the so-called idiopathic sciaticas.

In that year, 1929, Dandy¹³ reported 2 cases of transverse lesions of the cauda equina caused by free fragments of intervertebral disk tissue in the spinal canal. In both, the preoperative diagnosis had been malignant disease on account of the rapid march of signs and symptoms. Two quotations from his paper

Fig. 3.—Illustration from Dandy's paper, showing the fragment in situ.

sensory paralysis, loss of reflexes and of rectal and vesical control. The lesion is undoubtedly of traumatic origin.

In his summary he stated:

This lesion offers a pathologic basis for cases of "so-called sciatica," especially bilateral sciatica.

Dandy's article did not attract the attention that it deserved. As one looks back, it is easy to see the reasons. His reported cases were but 2 in number; they were both cases of complete transverse lesions; no attempt was made to correlate the lesions in these cases with the enchondromas, and not sufficient evidence was brought forward to prove the connection of the lesion he described with chronic unilateral sciatica. Nevertheless, one must remember that he was the first to report 2 cases in which there was surgical treatment for rupture of the intervertebral disk and the first to postulate that such fragments might be a cause of sciatica.

Fig. 4.—Illustration from Dandy's paper. The fragment after removal.

Alajouanine and Petit-Dutaillis¹⁴ and Crouzon, Petit-Dutaillis and Christophe¹⁵ reported 2 similar cases, calling the lesion a fibrocartilaginous nodule. Bucy¹⁶ reported 1 case and collected 15 other similar cases from the literature. He spoke of 3 or more cases reported to him by Peet¹⁷ in a

are given to show the importance of it and to emphasize the clarity of Dr. Dandy's reasoning from the material he presented:

The lesion is a completely detached fragment of cartilage from an intervertebral (lumbar) disk and is surrounded by serum. It bulges dorsally into the spinal canal as a tumor and by compressing the roots of the cauda equina causes motor and

personal communication. Bucy called the lesion in his case an enchondroma.

There the matter stood. Neurosurgeons were showing definite interest in these lesions, but with considerable diversity of opinion as to the character of the pathologic process. It had been suggested that these lesions might be responsible for certain of the fulminating cases of sciatica, particularly those in which transverse lesions developed. No one, to my knowledge, had endeavored to prove that the "enchondroma," the "ecchondroma," the "fibrocartilaginous nodule" or even the lesions in Dandy's 2 cases of detached cartilaginous fragments were related to the common complaint "chronic sciatica" as known to the orthopedist or the neurologist.

SURGICAL EXPERIENCES AND STUDIES

On July 30, 1930, I operated on T. D. Dr. C. S. Kubik, at that time in charge of the Department of Neuropathology and now Neuropathologist and also Chief of Neurology at the Massachusetts General Hospital, made a remark which stayed in my memory,

d the lower portion of the cauda equina to the right. It was incised and the

lean or infected

ation in full

removed piece-meal, allowing it to collapse and reure on the root. The wound was closed in layers wither drain outside the dura, and the patient was tra

Fig. 5.—Unretouched sketch from the operation sheet in the Massachusetts General Hospital record of K. N., showing the mass of cartilage beneath the first sacral nerve root.

though for a long time the seed so planted by Dr. Kubik did not germinate. The remark was: "I suppose we must call this lesion a tumor as you found a mass projecting into the spinal canal. The sections certainly look like normal cartilage." Dr. Kubik, in his formal report, stated that it was fibrous and hyaline cartilage and that, considering the location and the histologic appearance, the tumor was probably enchondroma. By this time, I had come to recognize the characteristic appearance of these curious "enchondromas" and to differentiate them from the frank enchondromas of bone. The former were hard small masses, which when incised extruded a mass of tissue looking for all the world like crumpled paper, while the latter were larger and softer and on section had a homogeneous almost translucent appearance.

In June 1932, a patient, K. N., was admitted to the Massachusetts General Hospital. He was recommended to the hospital by Dr. Frank Ober with the request that his case be studied by Dr. J. S. Barr and myself.

K. N. had been hurt in a skiing accident, and the history and observations were what are now known to be classic for ruptured intervertebral disk. Results of the roentgen examination were inconclusive, and examination with iodized oil as then carried out did not reveal any abnormalities. Examination of the spinal fluid revealed no evidence of dynamic block, but the total protein was 108 mg. per hundred cubic centimeters. In view of the fact that he was totally incapacitated and in pain, operation was advised.

The preoperative diagnosis was tumor of the cauda equina. After exploration of the whole lower cauda equina, a small mass was found pressing backward against the first sacral nerve root and arising from the fifth lumbar disk. The operative notes stated that the nodule was evidently an enchondroma. It was incised and the rolled up cartilage removed piecemeal, allowing it to collapse and relieving all pressure on the root.

Dr. Kubik's diagnosis was enchondroma. Figure 5 is an unretouched photograph of my drawing on the operation sheet of K. N.'s record.

Dr. Barr had been much interested in K. N. He had been struck by the fact that this patient had a dual syndrome, namely, some derangement of the low part of the back and accompanying sciatica. He was present at the operation. After the operation, either the same day or the next, Dr. Barr and I met in the corridor of the old Bulfinch Building and stopped to discuss the case. He stated that K. N.'s symptoms had followed an injury, and therefore the diagnosis of tumor was unsound. We recalled the fact that Dr. Kubik had stated that the microscopic sections in a similar case appeared to be normal cartilage, and Dr. Barr suggested that the lesion found in K. N.'s spine might be a Schmorl nodule. Dr. Barr examined the slides and was struck with the lack of cellular material in the specimen. He obtained some material from normal disks, had sections prepared and compared them with the specimen from K. N. The two tissues seemed to him and to Dr. Kubik to be identical, thus confirming the idea that the lesion was not a neoplasm.

Our first step was to review the pathologic specimens of all the patients with "enchondroma" of the spine operated on at the Massachusetts General Hospital. We found that, of these, six of the lesions were undoubted enchondromas or were unclassified and the remaining ten proved to be normal cartilage. This made us certain that we were dealing with a considerable group of lesions previously described as neoplasm, but undoubtedly of traumatic origin. These observations increased our interest. Therefore, we began reviewing the records of these cases for clinical evidence keeping in mind particularly the dual syndrome of low back derangement and sciatica in those cases in which the lesion was in the lumbar region. We were beginning to recognize the importance of the lesion. Desiring to confirm our conclusions, we delayed publication until we had further evidence.

During the next eight months, we found and operated on 7 patients, mostly by investigating the cases of chronic sciatica being followed in the Orthopedic Out-Patient Department of the Massachusetts General Hospital. On Dec. 19, 1932, six months after the operation on K. N., I operated on L. C., with a preoperative diagnosis of ruptured intervertebral disk, and found the lesion. In 1933, we felt that we had sufficient material to warrant publication. Our first paper was read before the New England Surgical Society on

Sept. 30, 1933. This paper was published in the *New England Journal of Medicine*, but not until Aug 2, 1934.¹⁸ Dr. Barr previously had read a paper, in the spring of 1933, before the Peter Bent Brigham Hospital Alumni Reunion, but this report received such an indifferent reception that it was not published.

After the reading of our paper and before its publication, Mauric's¹⁹ monograph on the intervertebral disk came to our attention. His conclusions, based in the main on an exhaustive and critical study of the literature, were similar to those of Barr and myself.

It was some time before resistance to this new explanation of the cause of sciatica quieted down. I can well remember asking permission of the Surgical Executive Committee of the Massachusetts General Hospital to give a clinical demonstration of our material at the meeting of the Massachusetts Medical Society. Permission was refused on the ground that the subject was far too controversial to be given a place in such a meeting. The lesion was difficult to demonstrate to a group, and I finally found that the best way to convince a skeptic was to have him scrub with me and see and feel the protruded fragment for himself before it was removed. Dr. James Love of the Mayo Clinic spent several days with us and then returned to Rochester to comb their cases of unexplained sciatica as we had combed our outpatient department. His series, I suppose, is today larger than that of any other single operator.

The problem of rupture of the cervical disk is perhaps more difficult than that of the lumbar disk. It was a natural sequence that brachial neuralgia should come under suspicion as soon as rupture of the lumbar disk was proved, particularly as the larger percentage of the "enchondromas" reported in the earlier literature were in the cervical region.

COMMENT

Such is the early story of our share, at the Massachusetts General Hospital, in the development of surgical treatment of the intervertebral disk. I shall not attempt to carry it beyond the reading of our paper in September 1933. The work goes on, as there are many problems that need further study. One thing is sure. Now that we are looking for this lesion, we find that sciatica and brachial neuritis are common complaints. Barr and I reported 19 cases in 1933. Today such cases are being reported in hundreds and even in thousands, and from these great groups of cases we should learn much.

In retrospect, it can be seen that the syndrome of the ruptured intervertebral disk lay for many years like the scattered pieces of a picture puzzle. All the pieces were there in the literature and, more importantly for us, in the cases in our own clinic at the Massachusetts General Hospital. Yet Dr. Barr and I might never have completed this picture had we not met that day to discuss at length the case of K. N. in the corridor of the old Bulfinch Building.

Dr. Barr and I both feel that every credit should be given to the long list of surgeons who faithfully reported their cases of "enchondromas," to those who reported the few cases recognized as rupture of the disk, to Schmorl and his co-workers for the discovery of Schmorl's nodules and especially to Dr. Walter

Dandy, who was the first, I believe, to hazard the guess, from the 2 cases which he reported, that this lesion might be responsible for sciatica.

SUMMARY

I should like to close leaving this thought: No discovery is ever made by one man or group of men. Had it not been for the reports of the various workers in neurosurgery, in pathology, in neurology and in orthopedics, the focusing of attention on rupture of the intervertebral disk and its importance as a clinical entity would have been impossible.

ABSTRACT OF DISCUSSION

DR. PHILIP LEWIN, Chicago: Many men have been nibbling at this problem, but they did not know what they were nibbling at. Dr. Mixter, Dr. Barr and Dr. Kubik deserve the greatest credit for combining all the links. Further study, observation and collaboration between the neurosurgeon and the orthopedic surgeon, who will teach the general practitioner, will help to clarify the problem of the intervertebral disk. Patients who really have it will be given early treatment. If the conservative treatment fails, then the surgical treatment should be given. There will not be so many recurrences or so many sciatic cripples.

COMBINED (ONE STAGE) SPLENECTOMY AND PORTACAVAL SHUNTS IN PORTAL HYPERTENSION

With Observations on Venous Shunts in the Postsplenectomy
Patient with Recurring Hemorrhage

LOUIS M. ROUSSELOT, M.D.
New York

It is now over fifty years since Guido Banti made his memorable declaration¹ on the etiologic, pathologic and clinical features of the "disease" which bears his name. For many years, no serious challenge of his theories was advanced.

Not until well after the turn of the century did occasional reports appear showing that a variety of unrelated pathologic lesions, all located in the portal venous bed, could produce the clinical picture described by Warthin.² In 1936, the initial report from the Spleen Clinic of the Presbyterian Hospital presented and supported a hypothesis at variance with the older, and then widely accepted, concept.³ This hypothesis has been reiterated in numerous communications.⁴

Continued experience has fortified the original position with a cumulative mass of supporting evidence. This material includes both clinical observations with long term follow-ups and postmortem confirmation of certain earlier cases in which, at the first reporting,

there was little knowledge of the primary lesion. The present understanding of the pathogenesis of Banti's syndrome is that it is the result of mechanical obstruction to the flow of blood within the portal bed. I believe that a state of "portal hypertension" is a concomitant in all cases of portal bed block. Ever since the original report of Thompson and Caughey⁵ it has been my practice to take manometric readings of the portal pressure at operation in all cases of suspected Banti's syndrome. In true congestive splenomegaly, readings are regularly found above 250 mm. of water, and levels above 400 mm. are not rare.

THE OBSTRUCTIVE FACTOR

As mentioned earlier, I believe that in congestive splenomegaly, the obstruction and portal hypertension may be produced by a variety of obstructive factors. This obstruction may be either intrahepatic or extrahepatic. The following outline summarizes my experience proved either at operation or at autopsy.

I. Intrahepatic

A. Cirrhosis of the liver

1. Laennec's cirrhosis
2. Schistosomiasis
3. Biliary cirrhosis
4. Infectious hepatitis

II. Extrahepatic

A. Stenosis of vein

1. Congenital
2. Acquired
 - (a) Phlebosclerosis

B. Compression of vein

1. Inflammatory cicatrix (following pancreatitis, cholangitis, etc.)
2. Pancreatic cyst
3. Tumor
4. Aneurysm of splenic artery

C. Thrombosis of vein

1. Inflammatory
2. Traumatic

D. Cavernomatous transformation of vein

Obviously, cirrhosis of the liver does not produce portal hypertension in all cases. In fact, in only a relatively small percentage of cases of cirrhosis of the liver, probably not over 20 per cent, associated congestive splenomegaly develops.

DIAGNOSIS

A searching discussion of the diagnostic criteria in this disease is not within the scope of this paper. The classic picture of splenomegaly with anemia, leukopenia and thrombopenia and a history of hematemesis with esophageal varices proved roentgenographically requires no great clinical acumen for the establishment of a diagnosis. If, in addition, tests of hepatic function indicate the presence of hepatic disease, then the diagnostic problem is further simplified. The most frequent errors in diagnosis, preoperatively, occur in patients without cirrhosis or without evidence of hemorrhage. The nonspecific blood

picture may be reproduced in leukemia, Gaucher's disease, hypersplenism, giant lymph follicle hyperplasia, lymphoblastoma and kala-azar. Bone marrow biopsy may often serve to differentiate some of the foregoing diseases, but its results are not infallible.

Prior to operation, besides complete hematologic studies, marrow or node biopsy and estimates of hepatic function and renal function should be made. Roentgenograms often demonstrate the presence and extent of esophageal varices.

SURGICAL TREATMENT OF PORTAL HYPERTENSION

The ultimate prognosis and selection of the type of surgical therapy in any given case of portal hypertension will depend on the following factors: (1) the nature of the obstructive factor, (2) its location, (3) the degree of portal hypertension and (4) the efficiency of collateral circulation.

Patients with an intrahepatic block, that is the cirrhotic patients, require the greatest exercise of judgment in timing, before operation is contemplated. When first seen, these patients may be greatly depleted because of varying grades of hepatic decompensation. Recurring gastrointestinal bleeding and ascites may further lower their vital protein stores. A prolonged medical regimen of a high protein, high carbohydrate and low fat diet with vitamin supplements and transfusions, may be necessary before the patient can be accepted as even a reasonable surgical risk.

In the noncirrhotic patients, the anemia associated with the congestive splenomegaly, or from preceding hematemesis, usually requires preoperative transfusion.

It is my firm conviction that splenectomy should always form the basic part of every surgical procedure, i. e., splenectomy with or without portacaval shunt rather than portacaval shunt alone without splenectomy. Most clinicians experienced in this field believe that the spleen in congestive splenomegaly exercises an inhibitory effect on blood formation. After splenectomy alone, there is usually a prompt rise of the granulocytes and thrombocytes to normal or well above normal levels. The erythrocytic rise is a slower process. Furthermore, the greatly enlarged spleen is a reservoir for a considerable volume of blood. The ease and rapidity of contractility of the spleen has been noted by many physiologists and clinicians. As the enlarged spleen in this disease probably carries some 40 per cent of total portal blood flow, its removal minimizes the inevitable sudden thrust of a large volume of blood on the already overburdened esophageal varices.

With a block in the splenic vein close to the hilum of the spleen, due to a thrombotic process or occlusion from pancreatitis or a pancreatic cyst, splenectomy alone will suffice, and a recurrence of hematemesis will be rare. When the block is at any point in the portal bed closer to the liver (that is, from the entry of the inferior mesenteric vein to the liver itself), a more radical operation must be considered. It is in this type of case with recurring gastrointestinal bleeding that combined splenectomy and portacaval shunt in one operation should be seriously considered. Experience has shown that in cases with hematemesis, in which the block is proximal to the inferior mesenteric vein, bleeding will invariably recur if splenectomy alone is done, and the eventual rate of mortality will approach 100 per cent.

In attempting to do shunts in the postsplenectomy case with recurring bleeding I usually found the splenic vein obliterated and unusable for anastomosis; hence my desire to effect a combined splenectomy and portacaval shunt as a one stage procedure.

The surgical treatment in this group of cases has been done entirely by three surgeons in the clinic at the Presbyterian Hospital, Dr. Allen O. Whipple, Dr. A. H. Blakemore and me. During the war years, Dr. Whipple and Dr. Blakemore operated in the cases herein reported and lately Dr. Blakemore and I. Dr. Whipple's and my earlier efforts to anastomose smaller branches of the mesenteric veins to smaller radicles of the caval system uniformly failed. Other reports reveal similar negative results.⁶ The size of the vessels used made the operation technically difficult, and, as this was before the use of anticoagulants, occlusion of the anastomosis regularly occurred.

Fig. 1.—Schematic view of portal circulation.

Blakemore early adopted his vitallium tube technic⁷ in an attempt to solve this problem. Most of my earlier cases were treated utilizing the endothelial lined tube. Some of these have an excellent follow-up record.

Practically all the cases handled in the past two years have been by the suture method with preservation of the kidney and the use of the larger veins in the portal bed. At the present time, the choice of portacaval shunts may be essentially divided into two main forms, i. e., either the splenorenal shunts or the portal vein to inferior vena cava anastomosis. The splenorenal diversion is used in most of the cases with an extrahepatic block. The lesion in these cases is predominantly in the portal vein, thus precluding the possibility of the Eck fistula. The Eck fistula, if used at all,^{7a} should be reserved principally in patients with cir-

rhosis. In figure 2 some of these procedures are schematically shown. Anatomic variations may dictate the use of other alternatives. Such substitutes are also illustrated. The following outline is a résumé of all the various combinations of operations utilized in this series of cases.

- I. Splenectomy, left nephrectomy; splenic vein to left renal vein
 - (a) end to end, vitallium tube
 - (b) end to end, by suture
- II. Splenectomy, no nephrectomy; splenic vein to left renal vein, end to side, by suture
- III. No splenectomy (Eck fistula); portal vein to inferior vena cava
 - (a) end to side, vitallium tube
 - (b) end to side, by suture

Fig. 2.—Illustrations of types of porta-caval shunts used in this group of cases. A, splenic vein to left renal vein; end to side. B, portal vein to inferior vena cava; end to side (Eck fistula). C, splenic vein to inferior vena cava; end to side. D, inferior mesenteric vein to left renal vein; end to side. E, superior mesenteric vein to inferior vena cava; end to side.

IV. Postsplenectomy

- (a) Superior mesenteric vein to inferior vena cava, end to side, by suture
- (b) Inferior mesenteric vein to left renal vein, end to side, by suture
- (c) Splenic vein to inferior vena cava, end to side, by suture
- (d) Inferior mesenteric vein to inferior vena cava, end to side, by suture
 1. Splenic vein to left renal vein, end to end, by tube
 2. Inferior mesenteric to left renal vein, end to end, by suture (double shunt at bifurcation of left renal vein)

Five patients with portal hypertension with previous splenectomy have been operated on. All these had recurring gastrointestinal bleeding for as long as ten years following their initial splenectomy. As men-

tioned previously, the mortality rate in these post-splenectomy bleeders will approach 100 per cent. Many of these cases are due to extrahepatic blocks, and death will inevitably follow intractable bleeding. The patients do not die from hepatic insufficiency, as cirrhosis is not a part of the pathologic picture.^{4a}

RESULTS

The initial and late results are briefly shown in tables 1 and 2. The hospital mortality rate in the cases of cirrhosis of the liver was 21.4 per cent, and the immediate cause of death is likewise listed in the accompanying tables. In the noncirrhotic group (albeit a smaller number of cases) the hospital mortality rate was 12.5 per cent.

The long term follow-up figures for the two groups are compared in table 2, and again the cirrhotic patients

show a slightly higher death rate. As the total number of cases is so small, one would be foolhardy to read too much into these figures. However, I believe that it is reasonable to predict that for some time to come the patients with cirrhosis will prove to be poorer risks in the immediate postoperative period and later on, with the ever present threat of hepatic decompensation.

Conversely, it is my opinion that those patients with an extrahepatic block will give more encouraging results over a similar period.

Table 3 presents a brief analysis of the late follow-up with reference to persistence of bleeding. In the cases listed as "successful" there was no recurrence of bleeding for the period of time listed; in the "moderately successful" cases there was less severe bleeding at longer intervals than before the shunt; in the "unsuc-

cessful" cases, although the patient was still alive, there continued to be recurrent bleeding of the same severity as before operation.

Five patients in this series had had previous splenectomy but continued to bleed. All of these had shunts of the types shown in the outline. Four of these had an extrahepatic block, and one had cirrhosis of the liver. At the time of writing the cirrhotic patient had

hypertension unless he is prepared to do a splenorenal anastomosis at the same operation, since this may be the only opportunity to construct a satisfactory shunt."

SUMMARY

The historical development of the modern concept of portal hypertension is reviewed. Reference is made to the importance of the obstructive factor and its site and nature.

Various surgeons in this country are attempting to solve the problem of continued gastrointestinal bleeding in this disease by means of portacaval shunts.

The experience of the Spleen Clinic of the Columbia-Presbyterian Hospital in 58 cases is presented. Although I realize it will take more years of continued effort and pooling of data by all those interested in this problem, I am encouraged with results to date and plan to continue the operation of combined (one stage) splenectomy and portacaval shunt.

My experience is in accord with that of Linton—a surgeon should not attempt splenectomy in a case of portal hypertension without being prepared to do a portacaval shunt. The initial operation usually offers the golden opportunity.

ABSTRACT OF DISCUSSION

DR. ROBERT R. LINTON, Brookline, Mass.: I would like to congratulate Dr. Rousselot on his excellent presentation of this subject and to acknowledge the important role he has played along with Dr. Whipple and Dr. Blakemore toward the development of it. An analysis of 108 cases of cirrhosis of the liver seen in the Massachusetts General Hospital from 1934 to 1945 revealed that 41 patients, or 38 per cent, died of hematemesis; and in the same period 20 patients with Banti's disease were seen, and 5, or 25 per cent, died from the same cause. It is the opinion at the Massachusetts General Hospital that the majority of these patients should be treated by splenectomy and end to side splenorenal shunt with preservation of the kidney. My co-workers and I recommend the left thoracoabdominal incision with resection of the ninth or tenth rib and partial division of the diaphragm. The results in the extrahepatic block, the so-called Banti's syndrome, have been better than in the group of cirrhosis, or the intrahepatic block. We have employed surgical treatment in 10 cases of the extrahepatic type, 6 male and 4 female patients, the ages ranging from 4 to 65 with a mean age of 27.7 years. The mortality rate in the Banti's group has been zero. The results in cases of the intrahepatic type have not been so good; there was a higher mortality rate. This we believe is because the patients have been much more critically ill, some of whom probably never should have been operated on. There were 15 in this group, 9 male and 6 female patients, ranging from 26 to 60 years of age with a mean age of 45 years. Eleven patients had splenectomy and splenorenal shunts with preservation of the kidney with a mortality rate of 28 per cent. The ones who have lived have not bled for periods of twelve to twenty-four months since the operation. Since January 1948, 9 patients with the intrahepatic type of block have been operated on and 8 have survived. I have two words of caution. First, this is not an easy type of operation. Second, as Dr. Rousselot has already stated, the surgeon should not do a splenectomy in a case of portal hypertension, especially in the Banti's group, unless he is prepared to do a splenorenal anastomosis at the same operation, since this may be the only opportunity to construct a satisfactory shunt.

DR. PAUL RAVENNA, Chicago: I wish to comment on the pathogenesis of the Banti syndrome. The idea that passive congestion alone is responsible for the splenomegaly is based on the fact that an obstacle to the venous flow of splenic blood is found in many cases. It overlooks the fact that sometimes such an obstruction is not found, either at the time of operation or at autopsy, though carefully searched for. In

been free of bleeding for nine months, one of the non-cirrhotic patients had an episode of bleeding while still in the hospital, but had subsequently been free of bleeding for eighteen months. Linton recently presented a series of 4 cases with shunt procedures.⁸ Three of the patients had had previous splenectomy. This report emphasized the technical difficulties in attempting shunts in the postsplenectomy patient. I am in complete accord with this author's statement, "... a surgeon should not do a splenectomy in a case of portal

8. Linton, R. R.: Porta-Caval Shunts in the Treatment of Portal Hypertension, *New England J. Med.* 238: 723, 1948.

some cases, therefore, an obstruction is not present. One must agree then that an obstacle is not necessary in the development of the Banti syndrome. Furthermore, some cases of fibrocongestive splenomegaly have been described in which a congenital anomalous vein provided a large wide open shunt between the splenic vein and the left renal vein. These are additional cases in which the splenomegaly could not be due to passive congestion. It is my feeling, therefore, that the mechanical obstruction may be complication, but is not the prime cause of the splenomegaly, and that one must recognize that the spleen is the organ primarily involved. I do not deny that mechanical obstruction may be of great importance—and of surgical importance—in cases of Banti syndrome, but I feel that it should be considered a complication and not the one primary factor.

DR. LOUIS M. ROUSSELOT: I greatly appreciate the provocative aspects of the remarks of both of my discussers, particularly Dr. Ravenna's. The problem of the discovery of a mechanical block has naturally been one that has interested my co-workers and me from the start of our studies. All that I can say in answer to Dr. Ravenna is that our evidence has been piling up over a period of years. We have yet to find a case, of the few that have come to autopsy, in which an obstruction was presupposed, in which we have not been able to prove its presence. It is only by a long range study that this question of causation can be finally answered; but with cumulative evidence one is certainly heartened and reassured. I am in complete accord with Dr. Linton's comments.

Council on Physical Medicine and Rehabilitation

The Council on Physical Medicine has authorized publication of the following article. HOWARD A. CARTER, Secretary.

REHABILITATION

HOWARD A. RUSK, M.D.
New York

To the physician the term "rehabilitation" has long connoted "the restoration of the handicapped to the fullest physical, mental, social, vocational and economic usefulness of which they are capable." In general usage, however, the term itself, during the past few years, has lost much of its significance, for it has been used to describe everything from correctional programs in modern penal institutions to the social and economic rebuilding of war devastated countries. With the developing emphasis placed on the processes of restoring handicapped workers, a new term has arisen which describes such processes more aptly and with more vitality. That term is "the third phase of medical care."

The modern concept of this third phase of medicine, which takes the patient from the bed to the job, springs both directly and indirectly from the war. The rehabilitation programs of the military services and the Veterans Administration demonstrated that planned, integrated programs of convalescent care stressing activity as an adjunct to definitive treatment could reduce the period of hospitalization, offset the deconditioning phenomena of bed rest and prevent the harmful psychologic sequelae which often result from extended hospitalization. The technics of physical rehabilitation and retraining for the severely handicapped developed by the military services also have profound implications for the even larger number of our civilian population who are disabled.

HIRING THE HANDICAPPED

Indirectly, the war also created interest in the third phase of medical care, for, because of the wartime man power shortage, many disabled civilians for the first time had an opportunity to take their place on production lines and to demonstrate that, with proper selective placement, they were efficient, reliable, safe employees. Prior to the war, many employers refused to hire handicapped workers on the grounds that they were more accident prone than the able-bodied. The industrial accident rate of eighty-seven of the great industrial plants in America, each having from 50 to 12,000 handicapped employees, has proved that concept fallacious. Studies of their experience show that 56 per cent found the accident rate of the handicapped lower than that of the able-bodied; 42 per cent found the rate the same as for the able-bodied, and only 2 per cent found it to be higher.

The Bureau of Labor Statistics of the Department of Labor has recently completed an exhaustive study of the work performance of 11,000 impaired and 18,000 matched unimpaired workers subjected to the same job incentives and exposed to the same job hazards.¹ The data taken from industry's own record show conclusively that the physically impaired person is not necessarily a handicapped worker if given reasonable job placement consideration. The two groups had identical frequency rates of nondisabling injuries, and the average rates of absenteeism showed no significant difference. The impaired workers, however, produced at a slightly better rate and had relatively fewer disabling work injuries than did unimpaired workers on the same jobs. No matter how different these physically impaired workers may have been in other respects, on the job they were just another group of workers able to meet their unimpaired fellow workers on an equal competitive footing.

It is well recognized that the compensatory laws of nature make adjustments in the abilities of the handicapped worker. We know that the loss of one sense leads to the sharpening of the other senses; that men with no legs develop more capable hands; that men without vision develop their sense of touch to the highest degree. Such compensatory abilities are not automatic; they come only through experience and training. To be of maximum vocational value, their development must be under skilled guidance.

ADVANCES IN REHABILITATION

Immediately following World War I, as today, there was a developing interest in increasing rehabilitation opportunities for the disabled. Unfortunately, this interest died in many quarters in the years between the wars. From it, however, did come some pioneer institutions and some needed legislation, such as the Federal Vocational Rehabilitation Act of 1920. The failure of the movement to gain sufficient stature to become an accepted part of medicine can be attributed to the fact that it was restricted largely to guidance, trade training and the purely vocational aspects of rehabilitation. Few provisions were made for physical restoration or reducing the physical disabilities of the trainees. When the physical condition became static, a program of vocational rehabilitation was planned, "training around" the disability rather than attempting to reduce or eliminate it through medical procedures. In many instances a comparatively large expenditure of time and money was

Dr. Rusk is Professor and Chairman, Department of Rehabilitation and Physical Medicine, New York University College of Medicine.

1. The Performance of Physically Handicapped Workers in Manufacturing Industries, Bulletin 923, United States Department of Labor, Bureau of Labor Statistics, 1948.

necessary for vocational rehabilitation when, by the expenditure of a few weeks and a modest sum, the physical limitations could have been substantially reduced with an automatic increase in employment potentials. Such restrictions made it impossible for the state vocational rehabilitation programs operating under the Federal Office of Vocational Rehabilitation to give adequate service to their clients. Such failure is shown by the fact that, until the basic philosophy of this program was changed by the Barden LaFollette Act of 1943, in twenty-three years only 210,000 persons were rehabilitated, although over 1,000,000 persons were in need of such aid at any given time during that period.²

Although the underlying philosophy of the third phase of medical care is based on logic and common sense, basic and clinical research in medical rehabilitation has been minimal until the past few years. Studies done in the military services, the inquiries of Keys,³ Barr,⁴ and others into the deconditioning phenomena of bed rest, the numerous reports of Powers,⁵ Whipple,⁶ Dock,⁷ Menninger,⁸ Ghormley,⁹ and others on bed rest as it affects their particular specialties are indicative of an increasing mass of scientific data on which such concepts are based. This evidence has been reinforced by the studies of successful experience with the impaired worker in industry, the economic values of rehabilitation as shown by the Office of Vocational Rehabilitation and the success of the Veterans Administration Medical Rehabilitation Program.

REHABILITATION IN THE VETERANS ADMINISTRATION

There was, at the war's end, some skepticism of the value of medical rehabilitation in the Veterans Administration hospitals for veterans of World War I and those of the Regular Army who suffered from chronic illness and long-standing disabilities. Some physicians feared that young veterans of World War II would soon lose ambition, initiative and a desire for personal independence through association with older veterans who had developed "hospitalitis" as a result of boredom, frustration and hopelessness. In the veterans' hospitals where comprehensive, dynamic rehabilitation programs are now in operation, the results have been not only revealing but encouraging.

Typical of the results obtained in the Physical Medicine Rehabilitation program of the Veterans Administration is a study of 130 patients with chronic neurologic disease in one hospital, all but 2 of whom were World War I veterans, and many of whom had not been out of bed in ten years.¹⁰ After nine months of physical medicine rehabilitation, 25 had left the hospital and were employed; 40 others had been discharged to their homes capable of light work, and, of those remaining, 30 were ambulatory and undergoing advanced rehabilitation and 25 were capable of some self care. All but

10 of the group had shown worth while permanent improvement. With a five year expectancy of these patients and a per patient day hospitalization cost of over \$12, rehabilitation of this one group has saved the government, and eventually the taxpayer, over \$1,125,000. It would seem logical that a similar program for the civilian chronically ill would result in comparable savings.

In another study at the Veterans Administration Hospital at Manhattan Beach in Brooklyn, through rehabilitation, 74 of a group of 126 patients suffering from such diseases as arthritis, multiple sclerosis, paralysis and Berger's, Parkinson's and heart disease have been discharged from the hospital and are now at home taking care of themselves.¹¹ All but 13 of the original 126 patients have recovered all or part of their ability for self care. At the beginning of this program, 83 of these veterans were "completely hopeless," but 49 in that group have been rehabilitated to the point of complete independence, and the remainder are capable of self care.

The experience of the Federal Office of Vocational Rehabilitation has also shown how rehabilitation pays off economically. During 1944, 43,997 persons underwent rehabilitation under the joint federal-state vocational rehabilitation programs. Of this group, 22 had never held jobs, and 90 per cent were not employed at the time they started their rehabilitation. Their average annual wage after rehabilitation was \$1,768, as compared with \$148 before. The cost of their rehabilitation was but \$293 per case, a single rather than annually recurring expenditure.¹²

These spectacular results are not attributable to the short labor market of the war. The approximately 44,000 persons rehabilitated in 1947 are now earning at a rate exceeding \$70,000,000 a year, and this year they will pay over \$5,000,000 back to the federal government in federal income taxes alone. The average rehabilitant was 31 years of age. If he works during 85 per cent of his life expectancy, he will pay \$10 in federal income taxes for each dollar the federal government has invested in his rehabilitation.¹³

Prior to rehabilitation, many of these persons now wholly or partially independent were on local relief rolls at an annual cost of \$300 to \$600 per case. In a study of such cases made in 1947 in Michigan, the relief costs of 400 cases were approximately \$250,000 per year. This same group, after rehabilitation, had been removed from the relief rolls, for they were earning more than \$600,000 a year. In another state, the program gave rehabilitation services to a young man of 21 who was drawing \$30 a month, or \$360 a year, in aid to the blind. He was trained to operate a vending stand, and at the end of his first year on the job paid \$250 in income taxes.

THE EXTENT OF THE DISABILITY

The lack of a systematic approach requiring the reporting of cases of physical disability to a central agency, together with varying subjective interpretations of "what constitutes a handicap," makes it difficult to stake out the boundaries of the field of rehabilitation and services to the handicapped in any quantitative fashion.

REHABILITATION

HOWARD A. RUSK, M.D.
New York

To the physician the term "rehabilitation" has long connoted "the restoration of the handicapped to the fullest physical, mental, social, vocational and economic usefulness of which they are capable." In general usage, however, the term itself, during the past few years, has lost much of its significance, for it has been used to describe everything from correctional programs in modern penal institutions to the social and economic rebuilding of war devastated countries. With the developing emphasis placed on the processes of restoring handicapped workers, a new term has arisen which describes such processes more aptly and with more virility. That term is "the third phase of medical care."

The modern concept of this third phase of medicine, which takes the patient from the bed to the job, springs both directly and indirectly from the war. The rehabilitation programs of the military services and the Veterans Administration demonstrated that planned, integrated programs of convalescent care stressing activity as an adjunct to definitive treatment could reduce the period of hospitalization, offset the deconditioning phenomena of bed rest and prevent the harmful psychologic sequelae which often result from extended hospitalization. The technics of physical rehabilitation and retraining for the severely handicapped developed by the military services also have profound implications for the even larger number of our civilian population who are disabled.

Dr. Rusk is Professor and Chairman, Department of Rehabilitation and Physical Medicine, New York University College of Medicine.

HIRING THE HANDICAPPED

Indirectly, the war also created interest in the third phase of medical care, for, because of the wartime man power shortage, many disabled civilians for the first time had an opportunity to take their place on production lines and to demonstrate that, with proper selective placement, they were efficient, reliable, safe employees. Prior to the war, many employers refused to hire handicapped workers on the grounds that they were more accident prone than the able-bodied. The industrial accident rate of eighty-seven of the great industrial plants in America, each having from 50 to 12,000 handicapped employees, has proved that concept fallacious. Studies of their experience show that 56 per cent found the accident rate of the handicapped lower than that of the able-bodied; 42 per cent found the rate the same as for the able-bodied, and only 2 per cent found it to be higher.

The Bureau of Labor Statistics of the Department of Labor has recently completed an exhaustive study of the work performance of 11,000 impaired and 18,000 matched unimpaired workers subjected to the same job incentives and exposed to the same job hazards.¹ The data taken from industry's own record show conclusively that the physically impaired person is not necessarily a handicapped worker if given reasonable job placement consideration. The two groups had identical frequency rates of nondisabling injuries, and the average rates of absenteeism showed no significant difference. The impaired workers, however, produced at a slightly better rate and had relatively fewer disabling work injuries than did unimpaired workers on the same jobs. No matter how different these physically impaired workers may have been in other respects, on the job they were just another group of workers able to meet their unimpaired fellow workers on an equal competitive footing.

It is well recognized that the compensatory laws of nature make adjustments in the abilities of the handicapped worker. We know that the loss of one sense leads to the sharpening of the other senses; that men with no legs develop more capable hands; that men without vision develop their sense of touch to the highest degree. Such compensatory abilities are not automatic; they come only through experience and training. To be of maximum vocational value, their development must be under skilled guidance.

ADVANCES IN REHABILITATION

Immediately following World War I, as today, there was a developing interest in increasing rehabilitation opportunities for the disabled. Unfortunately, this interest died in many quarters in the years between the wars. From it, however, did come some pioneer institutions and some needed legislation, such as the Federal Vocational Rehabilitation Act of 1920. The failure of the movement to gain sufficient stature to become an accepted part of medicine can be attributed to the fact that it was restricted largely to guidance, trade training and the purely vocational aspects of rehabilitation. Few provisions were made for physical restoration or reducing the physical disabilities of the trainees. When the physical condition became static, a program of vocational rehabilitation was planned, "training around" the disability rather than attempting to reduce or eliminate it through medical procedures. In many instances a comparatively large expenditure of time and money was

1. The Performance of Physically Handicapped Workers in Manufacturing Industries, Bulletin 923, United States Department of Labor, Bureau of Labor Statistics, 1948.

necessary for vocational rehabilitation when, by the expenditure of a few weeks and a modest sum, the physical limitations could have been substantially reduced with an automatic increase in employment potentials. Such restrictions made it impossible for the state vocational rehabilitation programs operating under the Federal Office of Vocational Rehabilitation to give adequate service to their clients. Such failure is shown by the fact that, until the basic philosophy of this program was changed by the Barden LaFollette Act of 1943, in twenty-three years only 210,000 persons were rehabilitated, although over 1,000,000 persons were in need of such aid at any given time during that period.²

Although the underlying philosophy of the third phase of medical care is based on logic and common sense, basic and clinical research in medical rehabilitation has been minimal until the past few years. Studies done in the military services, the inquiries of Keys,³ Barr,⁴ and others into the deconditioning phenomena of bed rest, the numerous reports of Powers,⁵ Whipple,⁶ Dock,⁷ Menninger,⁸ Ghormley,⁹ and others on bed rest as it affects their particular specialties are indicative of an increasing mass of scientific data on which such concepts are based. This evidence has been reinforced by the studies of successful experience with the impaired worker in industry, the economic values of rehabilitation as shown by the Office of Vocational Rehabilitation and the success of the Veterans Administration Medical Rehabilitation Program.

REHABILITATION IN THE VETERANS ADMINISTRATION

There was, at the war's end, some skepticism of the value of medical rehabilitation in the Veterans Administration hospitals for veterans of World War I and those of the Regular Army who suffered from chronic illness and long-standing disabilities. Some physicians feared that young veterans of World War II would soon lose ambition, initiative and a desire for personal independence through association with older veterans who had developed "hospitalitis" as a result of boredom, frustration and hopelessness. In the veterans' hospitals where comprehensive, dynamic rehabilitation programs are now in operation, the results have been not only revealing but encouraging.

Typical of the results obtained in the Physical Medicine Rehabilitation program of the Veterans Administration is a study of 130 patients with chronic neurologic disease in one hospital, all but 2 of whom were World War I veterans, and many of whom had not been out of bed in ten years.¹⁰ After nine months of physical medicine rehabilitation, 25 had left the hospital and were employed; 40 others had been discharged to their homes capable of light work, and, of those remaining, 30 were ambulatory and undergoing advanced rehabilitation and 25 were capable of some self care. All but

10 of the group had shown worth while permanent improvement. With a five year expectancy of these patients and a per patient day hospitalization cost of over \$12, rehabilitation of this one group has saved the government, and eventually the taxpayer, over \$1,125,000. It would seem logical that a similar program for the civilian chronically ill would result in comparable savings.

In another study at the Veterans Administration Hospital at Manhattan Beach in Brooklyn, through rehabilitation, 74 of a group of 126 patients suffering from such diseases as arthritis, multiple sclerosis, paralysis and Berger's, Parkinson's and heart disease have been discharged from the hospital and are now at home taking care of themselves.¹¹ All but 13 of the original 126 patients have recovered all or part of their ability for self care. At the beginning of this program, 83 of these veterans were "completely hopeless," but 49 in that group have been rehabilitated to the point of complete independence, and the remainder are capable of self care.

The experience of the Federal Office of Vocational Rehabilitation has also shown how rehabilitation pays off economically. During 1944, 43,997 persons underwent rehabilitation under the joint federal-state vocational rehabilitation programs. Of this group, 22 had never held jobs, and 90 per cent were not employed at the time they started their rehabilitation. Their average annual wage after rehabilitation was \$1,768, as compared with \$148 before. The cost of their rehabilitation was but \$293 per case, a single rather than annually recurring expenditure.¹²

These spectacular results are not attributable to the short labor market of the war. The approximately 44,000 persons rehabilitated in 1947 are now earning at a rate exceeding \$70,000,000 a year, and this year they will pay over \$5,000,000 back to the federal government in federal income taxes alone. The average rehabilitant was 31 years of age. If he works during 85 per cent of his life expectancy, he will pay \$10 in federal income taxes for each dollar the federal government has invested in his rehabilitation.¹³

Prior to rehabilitation, many of these persons now wholly or partially independent were on local relief rolls at an annual cost of \$300 to \$600 per case. In a study of such cases made in 1947 in Michigan, the relief costs of 400 cases were approximately \$250,000 per year. This same group, after rehabilitation, had been removed from the relief rolls, for they were earning more than \$600,000 a year. In another state, the program gave rehabilitation services to a young man of 21 who was drawing \$30 a month, or \$360 a year, in aid to the blind. He was trained to operate a vending stand, and at the end of his first year on the job paid \$250 in income taxes.

THE EXTENT OF THE DISABILITY

The lack of a systematic approach requiring the reporting of cases of physical disability to a central agency, together with varying subjective interpretations of "what constitutes a handicap," makes it difficult to stake out the boundaries of the field of rehabilitation and services to the handicapped in any quantitative fashion.

Although a census of such conditions has been proposed on several occasions (legislation calling for an exhaustive census of the physically handicapped was introduced in Congress by Senator Johnson of Colorado on March 15, 1948)¹⁴ there has never been a complete survey of the extent of disability in the United States. The most comprehensive source of information at present is the National Health Survey, conducted by the United States Public Health Service in 1935-1936.¹⁵ In this survey, 800,000 families in eighty-three cities and twenty-three rural areas of nineteen states were studied. The reliability of this study has been demonstrated in other extensive surveys on the extent of chronic disease and crippling conditions,¹⁶ and although results are not strictly comparable, because of different methods of enumeration, they bear out the fact that the National Health Survey is probably the best source available for such statistics, although later studies indicate that its results are conservative.

Although the focus of attention has been the disabled veteran, the extent of disability among our civilian population is far greater. There were 20,500 amputations during World War II, but over 120,000 major amputations during this same period among our civilian population.¹⁷ Approximately 1,500 men were blinded while in military service during the last war, but 60,000 civilians lost their sight during this period. Some 265,000 men were permanently disabled as a result of combat injuries during the war, but 1,250,000 civilians were permanently disabled by disease and accidents in the corresponding four years.¹⁸

There were some 23,000,000 persons in the United States handicapped to some extent by disease, accidents, maladjustment or war.¹⁹ One third of all draftees were rejected as unfit, and more than 1,000,000 had to be discharged shortly after induction.²⁰ In 1946, 10,400,000 persons suffered disabling accidents, and, of these 370,000 were disabled permanently.²¹ It is estimated that there are over 7,000,000 persons in the United States disabled by diseases of the heart and arteries, 6,850,000 from rheumatism and arthritis and 2,600,000 from orthopedic conditions.²²

These are the numbers, but they cannot tell the story of pain, anxiety, suffering and all the vital secondary problems that disease and disability leave in their wake. Aside from pain and wearing personal and family anguish, the economic costs of disease and disability are staggering.

CHRONIC DISEASE

Today, as medical science moves forward in the prevention and cure of infectious disease, chronic illness has become the nation's primary medical problem. In

1900, seven chronic diseases (cancer, diabetes, intracranial lesions of vascular origin, diseases of the heart, diseases of the arteries, cirrhosis of the liver and acute and chronic nephritis) were responsible for 25.7 per cent of all deaths in New York State. Between 1900 and 1940, a period in which the population of New York State increased by 85 per cent and the total number of deaths increased by only 13 per cent, the number of deaths from this group of chronic diseases increased by 200 per cent; it now includes over two thirds of all deaths in the state.²³

Whereas diabetes ranked twenty-seventh and arteriosclerosis thirty-fourth as causes of death in 1900, they were eighth and tenth in 1944.²⁴ Added to this is the tremendous long term toll of chronic illness and disability. Acute infectious disease usually results in rapid recovery or death, but chronic illness may linger for years. Its social and economic costs cannot be measured by mortality tables alone.

One of the principal causes of the increasing prevalence of chronic disease has been the great advances in medical and surgical care which have prevented death and produced an aging population. Two thousand years ago the average length of life was 25 years; at the turn of the century it was 49; today it is 66. In 1900, 1 person in 25 was 65 years of age or older; it is estimated that in 1980 the ratio will be 1 in 10. The chances are now 2 out of 3 that a young man now starting his working life at the age of 18 will live to his retirement age of 65. A 45 year old man today has 70 in 100 chances of reaching the age of 65, and the chances for a 55 year old man are 78 in 100. White men now at the age of 65 can expect to live an additional twelve and one-half years on the average, and white women an average of fourteen and one-quarter years.²⁵

As persons become older, their medical needs change, and they require more medical service. In 1940, the 26.5 per cent of the nation's population over 45 required over half the nation's medical services. By 1980, it is expected that the number of persons over 45 will constitute nearly half of the population.

The incidence of chronic disease is definitely related to economic status. It develops most frequently among families of low income, and when it strikes, results in further reduced income and depletion of financial reserves. In the National Health Survey of 1936, chronic illness was found to be nearly twice as great among persons on relief as among those earning \$3,000 a year and over. A more recent study in Illinois showed that 23 per cent of all public assistance recipients was chronic invalids.²⁶ In Connecticut, the percentage of old age assistance are chronically ill.²⁷

As chronic disease is usually nonreportable, reliable statistics as to its extent are difficult to find. Most currently used figures spring from the National Health Survey, from which the figure of 23,000,000 was derived. Later reports, based on smaller samplings,

however, have indicated that chronic disease is even more prevalent. In a recent survey in New Haven conducted by the School of Public Health of the Yale University College of Medicine, it was found that 121 persons for each 1,000 in the population suffered from chronic illness and that one third of this number were totally disabled.²⁹

Although chronic disease is more prevalent in older persons, authorities state that 16 per cent of all persons with known chronic disease are under 25 years of age. The Yale study found the percentage to be 33.

REHABILITATION IN GENERAL HOSPITALS

Though it would seem logical that medical rehabilitation would be an important service in every civilian general hospital, there has been little or no attempt until recently to establish such programs in civilian hospitals. Of the 1,468,714 hospital beds in the United States in 1946, 44 per cent were in general hospitals, but these 641,331 beds cared for over 92 per cent of all patients.³⁰ Rehabilitation, in varying degrees, has been available in some tuberculosis, mental and other specialized hospitals, but little provision has been made for dynamic convalescent care and rehabilitation for the over 14,000,000 persons who are patients in general hospitals each year.

The first comprehensive, total, medical rehabilitation program in any community hospital in this country was started in the spring of 1947 at Bellevue Hospital in New York. Operated under the professional direction of the Department of Rehabilitation and Physical Medicine, the service has facilities for 80 patients and offers a program of physical medicine, physical therapy, occupational therapy, corrective physical rehabilitation, social service, corrective speech, psychologic services, vocational guidance, education and planned recreation. It operates as a service department to the other departments of the hospital, in much the same manner as the roentgenologic department and laboratory, and treats both inpatients and outpatients on reference from the other services of the hospital.

The rehabilitation service in Bellevue Hospital, which will be enlarged to six hundred beds when presently planned construction is completed, is the first step in a plan by the Department of Hospitals of the City of New York to provide all patients in municipal hospitals of the city with medical rehabilitation services. The extent to which this rehabilitation has entered into future planning in New York City, in both public and private hospitals, is shown by a recent report of the Hospital Council of Greater New York, in which it was suggested that 25 per cent of the bed capacity of the city's general hospitals should be allocated for convalescence and rehabilitation.³⁰ This would mean one such bed for each 1,000 of the city's population.

The interest in extending medical rehabilitation services in general hospitals is not limited to New York or other large urban areas. The Veterans Administration has recently established such services as major departments, with specified bed allocations in all Veterans Administration Hospitals. Today, there are approximately one hundred and fifty communities in the nation which have expressed interest in establish-

ing rehabilitation centers.³¹ In some communities, such centers will be a part of, and will be located within, community general hospitals. In others, they will be adjacent to a community hospital. In still others, they will be separate community centers serving a number of hospitals. It is significant, however, that most are following the recommendations of the Baruch Committee on Physical Medicine that such centers be medically directed, and be associated with civilian hospitals and medical schools if possible.³²

THE INSTITUTE OF REHABILITATION AND PHYSICAL MEDICINE

This is the pattern being followed in the new Institute of Rehabilitation and Physical Medicine which recently opened as one of the first operating units of the new New York University-Bellevue Medical Center. Patterned after the recommendations of the Baruch Committee, the institute offers a complete program of physical medicine and rehabilitation, including physical rehabilitation and retraining, psychosocial adjustment and vocational evaluation and guidance for physically handicapped persons. It provides an integrated program of physical therapy, occupational therapy, physical rehabilitation, social service, vocational guidance and testing, and recreation, designed to teach the patient who has a physical disability "to live within the limits of his disability, but to the hilt of his capabilities." With facilities to care for an inpatient census of 30 and a daily outpatient load of 100, the institute places special emphasis on retraining in elevation, ambulation, crutch walking and the physical skills necessary for the activities inherent in daily living.

The institute's service and facilities are available to any patient, either on an inpatient or outpatient basis, who, in the opinion of the referring physicians and the institute's staff, could benefit from rehabilitation and retraining. It is expected that the majority of patients will be those needing definitive physical medicine or rehabilitation as the result of injuries, arthritis, orthopedic and neurologic disabilities, and diseases of the heart and arteries. Special facilities are available for a limited number of paraplegic and hemiplegic persons. Although the institute is not prepared to do vocational training of the handicapped *per se*, special workshops are available for vocational evaluation and guidance and job hardening under medical supervision for patients with arrested tuberculosis and cardiac disease. Complete vocational and guidance services are available for all types of persons with physical disabilities.

One of the special features of the institute is the prosthetic service, in which consultation and recommendations are made on the selection, fitting and adjustment of prosthetic devices of all types, and intensive training is given in their use. The institute does not manufacture or sell prosthetic devices, but has skilled technicians available for services for all types of amputations and for the minor adjustments and fittings frequently necessary to make artificial limbs more comfortable and efficient to the wearer.

Although we have in this country the finest institutions in the world for definitive medical care and for vocational training, outside of the military services

and the Veterans Administration there are but a small handful of civilian agencies and organizations equipped to provide for the patient with a physical disability the necessary retraining in physical skills which are a requisite for later vocational training. The physician in the past has thought too much about the physiologic and clinical aspects of the patient's disability. The vocational counselor too frequently has thought only in terms of physical skills which could be utilized vocationally. Between the two, however, there is a wide area through which most physically handicapped persons must go when their definitive medical care is completed but before they are ready to undergo vocational training. In this area lies the physical retraining in skills necessary for the carrying on of the activities inherent in daily living and common to all types of work.

Except in a few isolated instances, the physically handicapped person must be retrained to walk and travel, to care for his daily needs, to use normal methods of transportation, to use ordinary toilet facilities, to apply and remove his own prosthetic devices, and to communicate either orally or in writing. These are such simple things that they are frequently overlooked, but the personal, vocational and social success of the handicapped person is dependent on them.

THE PRACTICE OF REHABILITATION

The practice of rehabilitation for any doctor begins with the belief in the basic philosophy that the doctor's responsibility does not end when the acute illness is ended or surgery is completed; it ends only when the patient is retrained to live and work with what is left. This basic concept of the doctor's responsibility can be achieved only if rehabilitation is considered an integral part of medical service. Any program of rehabilitation is only as sound as the basic medical service of which it is a part. The diagnosis and prognosis must be accurate, for it is on them that the feasibility of retraining is determined.

In addition to the general diagnostic studies, the medical evaluation of the orthopedically handicapped must include muscle tests, determination of joint range of motion and tests for the inherent needs in daily living. In the rehabilitation service at Bellevue Hospital, a check list of ninety-six items is used to determine these factors. They include: (1) bed activities, such as moving from place to place in bed, and the ability to sit erect; (2) toilet activities; (3) eating and drinking; (4) the ability to dress and undress, such as tying shoe laces, manipulating buttons, zippers and other fasteners, and applying and removing braces; (5) hand activities—for example, winding a watch, striking a match and using various door knobs and latches; (7) wheel chair activities, getting from the bed to the wheel chair, the wheel chair to bed, and in and out of the bathtub, and (8) elevation activities, which include the needed abilities for walking, climbing and traveling.

•At first glance, such a test list sounds formidable and time consuming, but, in reality, the information may be easily obtained by a therapist, nurse, a well trained volunteer or a member of the patient's family. From special check sheets used for charting the activity accomplishments, information is readily available both on the status of the patient at the time of admittance and his progress while undergoing rehabilitation.

The use of such a check list is particularly helpful if personnel are not available to do definitive muscle

testing and accurate range of motion determination, for the daily activities test can be completed in the hospital, the physician's office or the patient's home. The subsequent training program is designed to teach the patient the various skills and activities which he cannot perform.

In Bellevue Hospital and the Institute of Rehabilitation and Physical Medicine, after the basic medical work-up, and the range of motion, muscle and needs of daily living tests, the physician, in conference with other staff members, prescribes a five-hour a day program for the patient. These prescribed activities include training in the ambulation and elevation rooms and the remedial gymnasium, occupational therapy, physical therapy, speech therapy or any other activity which may be helpful in meeting the specific needs of the patient.

In a comprehensive rehabilitation program, vocational guidance specialists should also be available to do guidance and testing, in order that the patient may be started on a prevocational exploratory and work testing program as soon as it is medically feasible. However, good basic rehabilitation can be carried out with the personnel available in the ordinary general hospital, if such a program is properly organized, supervised and prescribed by the physician.

The rehabilitation of the hemiplegic person is a typical example. There are a number of simple progressive procedures in the rehabilitation of the hemiplegic, who suffers from one of the commonest disabilities seen in general practice. In the early stages of treatment, the following procedures should be instituted to prevent deformities: (1) footboard or posterior leg splint to prevent foot drop; (2) sandbags to prevent outward rotation of the affected leg; (3) a pillow in the axilla to prevent adduction of the shoulder, and (4) quadriceps setting to maintain muscle strength. All of these procedures are relatively simple and require no special equipment. Their use, however, will prevent crippling anatomic deformities and hasten the rehabilitation of the patient.

The next procedure indicated is the institution of pulley therapy. This can be done simply with a small pulley attached to a goose neck pipe over the head of the bed, the ordinary clothes line rope being used with a 1 inch (2.5 cm.) webbing for the hand loop. With the stretching and passive exercise provided by pulley therapy, the range of motion can be increased and adhesions prevented.

Pulley therapy has the advantage over the usual stretching exercises that are done passively, for the patient, knowing his own pain threshold, will proceed to fully tolerated motion much more quickly. Pulley therapy can also be used to aid in the reestablishment of reciprocal motion patterns.

The patient, at this stage, should be encouraged to sit erect in order to reestablish balance. Speech therapy, if indicated, should be instituted at this time. In the absence of a trained speech therapist, the speech reeducation can be started under medical supervision by any teacher who has had some experience in this field. In the case of aphasia, it is well for the physician to point out to the patient and family the nature of the condition, in order that the inability to use the tools of language may not be interpreted as loss or diminishing of the ability to think and reason.

The next progressive stage in retraining the hemiplegic person is ambulation, which should be started

by: (1) the practice of balance in the standing position, progressing to parallel bars; (2) the teaching of a heel and toe gait to minimize clonus and to reestablish normal walking habits stressing reciprocal motion, and (3) a short leg brace, which will be needed in approximately half of all cases to correct foot drop. All of the equipment for training in ambulation is simple and readily obtained by the general practitioner. If parallel bars are not available, two kitchen chairs may be substituted.

In the advanced stages of retraining, ambulation is continued with (1) instruction in crutch walking, starting usually with the alternate four point gait, and (2) teaching elevation, stressing climbing steps, curbs, stairs and ramps. Concurrently with the training in ambulation, attention should be given to retraining in the activities of self care and daily living.

Obviously, the physician himself cannot undertake the actual administration of the retraining, but the therapist, nurse, volunteer or even a member of the family can conduct the activities under his supervision. With such a program, many of the complications usually following apoplexy can be avoided and a great deal of time and ability salvaged.

Although the general practitioner is forced to call on the services of medical specialists when dealing with amputee patients, he must assume the responsibility for preparing his patient physically and psychologically for the amputation and for seeing that the patient has the proper prosthetic device adequately fitted and is trained in its use.

One phase of the management of the amputee to which the physician should give particular attention is the immediate postoperative period while the stump is being shrunk in preparation for a prosthetic device. During this period of six to eight weeks the patient should be given graduated conditioning exercises in preparation for both crutch walking and the later use of the artificial limb, and measures should be taken to prevent anatomic deformities.

For example, it is not an uncommon practice in many hospitals, after an amputation above the knee, to elevate the stump on a pillow. However, if such elevation is maintained for as long as two weeks a flexion deformity will occur which will take from six to eight weeks of arduous, painful work before sufficient hyperextension can be regained for satisfactory walking.

In advising his patient on the selection of a prosthetic device, the physician must be aware that not all limbs are suitable for all amputees. In fact, he must realize that not all amputees can wear artificial limbs profitably. It has been noted on the rehabilitation service at the New York University College of Medicine that a person in the older age group with an amputation above the knee cannot, as a rule, profitably be trained to use a prosthesis if he is unable to perform a swing-through gait on crutches.

The physician must point out objectively to the patient those skills which the patient can expect to achieve with proper training and those skills which the patient has little chance of ever regaining. Extreme caution must be taken in the latter, however, as it is unwise to tell a patient what "he can't do," for this cannot be determined, in most cases, until the patient has had adequate training. Training is absolutely essential if the amputee is to be successfully rehabilitated.

Because of the hopeless outlook in multiple sclerosis, therapy in general has been directed toward symptomatic relief, and the approach has been a negative one. In rehabilitation, the disability, rather than the specific disease process which has produced it, is our primary consideration. In multiple sclerosis, as in any other chronic, progressive, crippling disease, the problems are the same. In considering a patient as to feasibility of successful training, progression of the disease must be carefully evaluated, for if the disease process outstrips training, such training is obviously wasted.

In rehabilitation, the primary consideration in working out a program for the severely disabled is to teach him to live, and, if possible, to work, with what he has left. Those capacities can be determined only through performance testing. It is impossible, through the analysis of the clinical manifestations of a disease such as multiple sclerosis, to determine what the sum total of the remaining physical capacities of the patient can be trained to do in the way of work or self care activities. In addition to general diagnostic studies, the medical evaluation of the patient with multiple sclerosis must include muscle tests, joint range of motion and tests for the inherent needs of daily living. These are of primary importance, for it is on their results that the patient's rehabilitation program is planned.

Too frequently, in rehabilitation, many of the basic skills necessary for effective daily living are overlooked. The patient is given numerous medical, psychologic and vocational services in preparation for employment, but retraining in the basic physical skills of ambulation, elevation and self care activities is neglected, with the result that the patient, being unable to walk, travel or care for his personal needs, is also unable effectively to utilize the other medical, psychologic, social and vocational services which he has received for richer and fuller living.

Retraining in the basic physical skills of daily living is primary; it is simply a matter of "first things first," for daily activity skills are the basis for all subsequent rehabilitation processes.

It has been found difficult in many instances to differentiate between muscular inability due to disease and that due to atrophy of disuse, and sometimes only a test period of conditioning exercise will provide this information, which is vital in the training program.

From the information gained by the tests for the factors of daily living, a suitable program is set up for the patient, designed to meet his particular needs. It has been noted, especially in hand activities and gait training, that persons long incapacitated from multiple sclerosis will have alienation and overcompensation of certain muscle groups. With muscle reeducation and definitive therapeutic exercise, it is often possible to accomplish much in correcting these conditions.

We approach the psychiatric-psychologic problem as a team—the psychiatrist, the social worker and the psychologist—working with the family as well as with the patient.

It has been found that the previous personality of a patient with multiple sclerosis does not conform to any particular pattern. There is immaturity in certain cases and a great deal of independence and relative maturity in other cases.

The main point is that after the patient's personality is thoroughly known by psychiatric examination,

psychologic study and social service investigation, then each problem, as it comes up, can be handled with the full knowledge of the limitations of the patient, psychologically and physically.

Multiple sclerosis offers one of the most challenging problems in the entire field of rehabilitation, both from the physical and the psychologic standpoint. Therapy in this field requires patient training and deep understanding. However, the results in the restoration of confidence and function, though far from satisfactory, have been gratifying.

The physician must also recognize that emotional trauma may be present in any patient who has suffered a severe physical disability. The sudden shock and realization of the possible economic and social consequences of permanent disability frequently produce fear and anxiety which become as handicapping to the worker as the original physical disability. Even at the Department of Rehabilitation and Physical Medicine at Bellevue Hospital, and at the Institute of Rehabilitation and Physical Medicine, where many of the patients have physical disabilities of long standing, it has been found that approximately one third of all patients have concomitant emotional problems of such severity that psychiatric attention is needed. Consequently, the full time services of a psychiatric team consisting of a psychiatrist, a clinical psychologist and a psychiatric social worker have been added to the staff.

When patients present themselves who are in need of psychiatric attention, it is the responsibility of the physician to recognize that need and see that proper referrals are made for such attention. In many instances where emotional problems are of a less severe nature, the general practitioner can resolve such problems. One of his greatest responsibilities with those patients who have severe physical disabilities is motivation—encouraging and convincing the patient that he can be rehabilitated. This motivation, to be most effective, must begin at the earliest possible moment following the accident or illness. The physician who knows something of rehabilitation can start at the time of the accident or crippling illness to allay the fears of his patient by giving him understanding, courage and hope predicated on an accurate knowledge of what can be done. He can interpret to the patient the findings of the specialist in words that are understandable and meaningful. He can explain to the patient the nature and extent of his disability, not in medical terms of the disability alone, but in terms of its effect on the vocational, social, economic, family and personal life of the patient. The physician must practice the art of medicine as well as the science.

Regardless of the type of disability, the responsibility of the physician to his patient cannot end when the acute injury has been cared for. It ends only when the physician has taken the responsibility for seeing that proper referral has been made to those agencies and institutions which are equipped to rehabilitate and retrain the patient with a residual physical disability. The physician who fails to see that those patients under his care receive the full benefits of modern methods of medical rehabilitation and retraining is in the same category as the physician who still persists in using dietary restriction alone in the management of diabetes, when insulin is available, for medical care is not complete until the patient has been trained to live and work with what he has left.

REPORT OF THE COUNCIL

The Council on Physical Medicine has authorized publication of the following article. HOWARD A. CARTER, *Secretary.*

THE COUNCIL ON PHYSICAL MEDICINE BECOMES THE COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

In 1944 it became apparent that Physical Medicine should include not only the employment of physical agents for therapy but also the employment of physical agents for diagnosis, and when it also became apparent that that branch of the specialty known as occupational therapy should also come within the purview of the Council, the Council on Physical Medicine recommended that its name should be changed from "the Council on Physical Therapy" to "the Council on Physical Medicine." The Board of Trustees of the American Medical Association approved this change in name in 1945.

During World War II and in this postwar period, the close relationships between physical medicine and the rapidly growing field of rehabilitation have become increasingly apparent. In our governmental hospitals and to an ever increasing extent in our civilian hospitals the services in physical medicine and rehabilitation have become inextricably conjoined. In the Army after World War II there was established a Physical Medicine Consultants Division which directs the activities not only in physical medicine but also in rehabilitation and physical reconditioning in all Army general hospitals. In the Veterans Administration, a central Physical Medicine Rehabilitation Service has been established which coordinates and directs the work in physical medicine and rehabilitation in all Veterans Administration hospitals. In our civilian teaching institutions, combined residencies in physical medicine and rehabilitation are being offered in rapidly increasing numbers.

Likewise, when, during its annual meeting, the Council on Physical Medicine conferred with representatives of the Council on Medical Education and Hospitals, it was agreed that the fields of physical medicine and rehabilitation were so closely related that it would be inadvisable to offer separate residencies or fellowships in these two branches. Therefore, it was the joint opinion of those present at this conference that a movement toward the development of more combined residencies in physical medicine and rehabilitation should be encouraged. It was agreed that those who direct existing approved residencies in physical medicine should be encouraged to include more complete instruction in rehabilitation and that the establishment of separate residencies in rehabilitation should not be approved.

It has become increasingly apparent to the members of the Council on Physical Medicine that the close relationships between physical medicine and rehabilitation must be recognized and that, while neither special field can or should absorb the other, the many interconnections should be indicated. There are phases of physical medicine (as in the definitive treatment of acute diseases by physical agents) which cannot be called rehabilitation and there are phases of rehabilitation (as in the psychosocial readjustment of the disabled person) which cannot be called physical medicine. Yet, for the most part, physical medicine and medical rehabilitation are closely interdigitated and it is apparent that it would be illogical for either physical medicine or medical rehabilitation to go its separate way.

Furthermore, the Council has become more and more involved with the various aspects of rehabilitation. The members of the Council desire to indicate that there are other special fields of medicine in which a similar joint terminology has been found essential. These include "dermatology and syphilology," "obstetrics and gynecology" and "psychiatry and neurology."

For these reasons, after mature deliberation, the Council on Physical Medicine has recommended to the Board of Trustees of the American Medical Association that, owing to the inevitable march of progress and the expansion of its interests into the field of rehabilitation, its name be changed once more and that hereafter it be designated as "the Council on Physical Medicine and Rehabilitation." It has been concluded that this is a fully logical and in fact highly desirable change, which would indicate more specifically the present status of the expanding field of medical activity with which the Council is concerned.

MEDICAL LICENSURE STATISTICS FOR 1948

FORTY-SEVENTH ANNUAL PRESENTATION OF LICENSURE STATISTICS BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

Donald G. Anderson, M.D., Secretary, and Anne Tipner

Licensure of Foreign Trained Physicians	315
Officers of State Boards of Medical Ex- aminers	317
BOARDS OF EXAMINERS IN THE BASIC SCIENCES	321
NATIONAL BOARD OF MEDICAL EXAM- INERS	323

Statistical compilations regarding medical licensure are presented annually in the State Board Number of THE JOURNAL. The report for 1948 constitutes the forty-seventh annual presentation. Data are included pertaining to (a) medical examining and licensing boards of the United States, the District of Columbia and the territories and possessions of the United States, (b) the boards of examiners in the basic sciences and (c) the National Board of Medical Examiners.

The computations presented are based on official records received throughout the year from the medical examining and licensing agencies of all states, Alaska, Hawaii and Puerto Rico, the nineteen boards of examiners in the basic sciences and the National Board of Medical Examiners. This presentation is made possible because of the wholehearted cooperation of these boards. The Council and THE JOURNAL gratefully acknowledge their appreciation to those who have supplied these data as well as other records furnished throughout the year.

The tables referring to medical licensing boards present figures pertaining to the number of candidates examined, the numbers licensed and the number who represent additions to the physician population. There are also included other pertinent data pertaining to the regulations for medical licensure. The state boards are discussed first, followed by the basic science boards and the National Board of Medical Examiners.

STATE BOARDS OF MEDICAL EXAMINERS

Licenses Issued

In 1948, 13,551 licenses to practice medicine were issued by the medical examining boards of the forty-eight states, the District of Columbia, Alaska, Hawaii and Puerto Rico. The number licensed in each state, by examination or by the endorsement of credentials, is shown in table 1. Of the 13,551 licenses issued, 5,967 were granted after examination and 7,584 by reciprocity and endorsement of state licenses or the certificate of the National Board of Medical Examiners.

Physicians certified in a given year after examination in all instances were not tested in that year. In twenty-five states, the District of Columbia, Alaska, Canal Zone, Hawaii, Puerto Rico and the Virgin Islands, the internship is a requisite for licensure. The

P—Passed; F—Failed.

licensing boards of some of these states permit the candidate to write the examination before completion of the internship and, if successful, issue and date the license on completion of the internship. Licenses are also withheld in some states for other technicalities. In general, also, the licenses of physicians examined in December are dated and issued early in the following year. Table 1, therefore, includes many who were examined in 1947 and a few in previous years, and the figures shown will not correspond with other tables which deal entirely with physicians examined for licensure within the year 1948.

Neither does this tabulation, particularly the endorsement group, represent entirely individuals but includes persons who may have been licensed in more than one state in a given year; nor does the total represent additions to the medical profession, since a

physician previously licensed in one state may be licensed by examination in a nonreciprocating state. In tables 12, 13 and 14 (see pages 310 and 311) can be noted the number who secured licenses for the first time and represent additions to the medical profession in the United States and its territories and possessions.

The greatest number of licenses during the last calendar year were issued in California, 1,751. New York licensed the next greatest number, 1,385, while more than 500 physicians were registered in Illinois, Ohio, Pennsylvania and Texas. No state licensed fewer than 25.

The number of licenses issued in 1948, as was true in two previous years, was greater than in any prewar year. Although in 1948 there were 892 fewer licenses registered than in 1947, there were increases recorded in 22 states as follows:

A recapitulation of totals pertaining to licenses issued for thirteen previous years and for 1948 by both examination and reciprocity or endorsement of credentials is included in table 3. The variations shown for the years from 1936 to 1941, inclusive, were the result of the noticeable increase in the licensure of graduates of foreign medical faculties. The accelerated program in medical schools which produced 20,662 graduates in the three year period from June 1942 to June 1945 likewise increased the numbers licensed. In 1946 and the two succeeding years the numbers licensed were almost double those of prewar years. This increase reflects the migration of medical officers. However, there was a decrease in 1947 and again in 1948 as compared with the all time high total for 1946.

In the fourteen year period 1935 to 1948, 143,684 medical licenses have been issued, 88,097 after examination and 55,587 by endorsement of credentials.

Candidates Examined by Medical Examining Boards

In table 2 are recorded data referring to those examined for medical licensure in 1948 by individual states, the District of Columbia, Alaska, Hawaii and Puerto Rico. For each there are given the numbers who passed and failed, the medical school of graduation,

TABLE 3.—*Licenses Issued, 1935-1948*

	Examination	Reciprocity and Endorsement	Total
1935.....	5,725	2,194	7,919

Totals.....	88,997	55,587	143,684

the percentage of failures by school as well as licensing board and the number of states in which graduates of a given school were examined. Medical schools in the United States which are no longer in existence, foreign faculties of medicine and unapproved schools are not listed by name, but the numbers examined in each state in these three categories are included following those for existing medical schools in the United States and Canada.

Throughout the last calendar year 6,560 were examined, of whom 5,840 passed and 720 failed. The candidates represented seventy approved medical schools of

the United States, nine approved medical schools of Canada, four medical schools in the United States now extinct, one hundred and five faculties of medicine and three licensing corporations of other countries, five unapproved institutions and six schools of osteopathy. Osteopaths who were granted the legal right to practice medicine, surgery, or both, by the medical examining boards are included in these statistics. Osteopaths in other states who were granted the privilege of special

practice by other than medical examining boards are excluded from these compilations.

Examination and reciprocity meetings have been scheduled at frequent intervals in recent years to facilitate licensure and to enable physicians to commence practice without undue delay. Later in this study there is included a tabulation giving the schedules for all states. Executive officers and members of examining boards are to be commended for thus assisting the veteran medical officer and others to begin practice at their new location as soon as possible. This cooperation, in view of the increase in volume of applications, is noteworthy.

Represented among the 6,560 examinees were 5,304 graduates of approved medical schools in the United States, of whom 3.3 per cent failed; 139 graduates of approved Canadian schools with 16.5 per cent failures; 15 who were graduated from medical schools no longer operating with 6.7 per cent failures; 636 graduates of faculties of medicine located in countries other than the United States and Canada, 51.5 per cent of whom failed; 302 graduates of unapproved institutions with

TABLE 5.—*Source of Candidates Examined for Licensure in the United States, 1948*

Medical Schools	Number of Schools	Number Examined	Number Passed	Number Failed	Percentage Failed

Schools of Osteopathy.....	6	164	102	62	37.8
Totals.....	199	6,560	5,840	720	10.9

42.7 per cent failures and 164 graduates of schools of osteopathy with 37.8 per cent failures.

As in table 1, the 6,560 examinees do not represent an equal number of individuals, since a candidate tested in more than one state in a calendar year is counted in each state. However, if a candidate failed more than once in a given state within the year, he is counted in that state as only one failure.

The greatest number of graduates of any one school examined was 214, representing Northwestern University Medical School, 98 of whom were tested in Illinois and 116 in twenty-seven other states. More than 150 graduates of five other schools applied for licenses last year; namely, University of Illinois (211) in twenty-six states, St. Louis University (156) in thirteen states, Hahnemann Medical College (154) in twenty-six states, Jefferson Medical College (166) in twenty-four states and Marquette University (174) in eighteen states. One hundred or more graduates of eleven other schools also were tested during the year.

Nineteen approved schools in the United States had no failures before medical licensing boards, twenty-nine less than 5 per cent and twelve between 5 and 10 per cent. There were ten schools with 10 per cent or more failures in state examinations. The over-all figures and percentages for failures are modified by data on those who were examined by the National Board of Medical Examiners in its final examination as well as those passing state tests (table 6, page 299).

Graduates of Northwestern University were examined in the greatest number of states, twenty-eight. University of Pennsylvania alumni were tested in twenty-seven states and the University of Illinois and

Hahnemann Medical College in twenty-six states. All other schools had their graduates examined in fewer than twenty-five states. Three schools had graduates examined in fewer than five states.

A total of 139 graduates of nine approved medical schools in Canada appeared for licensure in the United States in 1948 in twenty-five states, the District of Columbia, Hawaii and Puerto Rico. The figures are given for each licensing board by schools in table 1 and by totals in table 4. Of the 139 examinees, 23 (16.5 per cent) failed. California examined 28, New York 18, Illinois 16 and Maine 10, and all other states fewer than 10. Two Canadian schools had no failures before United States licensing boards. The lowest failing percentage was 4.8. The remaining schools had percentages higher than 8.

Graduates of osteopathic schools and of unapproved institutions were examined by sixteen states. Represented were 164 osteopathic graduates of whom 102 passed and 62, or 37.8 per cent, failed and 302 graduates of unapproved schools, of whom 173 passed and 129 (42.7 per cent) failed.

Graduates of foreign faculties of medicine were examined in twenty-eight states and Puerto Rico. There were 636 such graduates with 328, or 51.5 per cent, failures.

Fifteen graduates of schools no longer operating were tested in seven states, of whom 14 passed and 1 (6.7 per cent) failed.

In all six categories mentioned, 6,560 appeared before medical examining boards in 1948, of whom 5,840 passed and 720, or 10.9 per cent, failed.

Totals for the six categories are given in table 5. As already mentioned, from the United States approved schools there were 3.3 per cent who failed, as did 16.5 per cent of the Canadian graduates and 6.7 per cent of the graduates of extinct schools. The greatest percentage of failures represented three groups, foreign schools, unapproved schools and schools of osteopathy. In these groups 51.5, 42.7 and 37.8 per cent, respectively, failed. Those registered in these three groups are discussed separately later in an analysis of these statistics.

Elsewhere (see tables 12, 13 and 14, pages 310 and 311) are given figures referring to actual licentiates and additions to the medical profession.

Consolidated Examinations

A combination of the results of individual schools for two groups, i. e., those appearing for the state medical board examinations and for part III of the examinations of the National Board of Medical Examiners, is given in table 6. This table presents a more accurate picture of the performance of physicians from the individual schools in licensure examinations than is given in the preceding tables. In some instances, it will be noted, schools having a high percentage of failures before state licensing boards had few, if any, failures before the National Board. In 1948 there were 5,304 graduates of approved medical schools in the United States examined by state boards, of whom 3.3 per cent failed. In 1948, 1,685 graduates of these institutions appeared for part III of the examinations of the National Board, of whom 14, or 0.8 per cent, failed. In the consolidated figures the failures from approved medical schools in the United States were 2.7 per cent.

Of the Canadian graduates, 16.5 per cent failed state board tests and 15 per cent failed the combined tests. Only 9 graduates of foreign medical schools were tested

by the National Board. There is no comparison to be made of this group. There were none in the extinct medical school classification examined by the National Board. The National Board does not admit to its examinations the graduates of unapproved medical schools in the United States, and from foreign schools it admits only the graduates of the university medical schools of Great Britain and Ireland, provided these graduates have been licensed to practice in the country in which the school attended is located.

As mentioned in the preceding section, the total of all examined before medical licensing boards in the United States in 1948 was 6,560, of whom 5,840 passed and 720, or 10.9 per cent, failed. For both groups—state boards and the National Board—8,275 were examined; 7,540 passed and 735 (8.8 per cent) failed. The total percentage of failures was reduced less than 2 per cent because of the high percentage of failures before state boards by unapproved and foreign graduates. Sixty-four approved schools in the United States and four in Canada were represented in the National Board examinations.

Failures

Data recorded in table 7 refer to failures before medical licensing boards by licentiates of 1948. In presenting these statistics the United States is divided into two groups—the thirty-one states and the District of Columbia in which approved four year medical schools are located and those states and the territories and possessions which have no medical school within their boundaries. The figures include the number of licentiates who failed state board examinations prior to licensure and were graduates of a medical school located in the state in which they were examined and also the number of graduates licensed in a given state who obtained their professional training in schools in other states.

Practically all states require the applicant to receive a general average of 75 per cent in the medical license examination and at least 50 per cent in any one subject. In case of failure in not more than two subjects the applicant is permitted a second examination in those subjects within twelve months. A few states consider such persons as conditioned in the subjects in which they fail and do not report them to the office of the Council on Medical Education and Hospitals as failures. These examinees are not included in any of the tabulations which include failures. When their grades are raised after a successful reexamination they are recorded among those who passed.

Sixty-eight physicians failed examinations in the state in which they obtained their professional training. This occurred in nine states. Twenty-nine failed in New York. There were failures reported by twelve states among students who graduated from approved medical schools located in states other than the one in which they were licensed. Again, New York had the greatest number, 53. Twenty-three states reported no failures during the year from graduates of schools located in these states, and twenty states had no failures among graduates of schools located in other states. Seventeen states had no failures in either group.

In seventeen states having no medical schools, six reported failures. In all, 32 failed.

The total examined in the first group, states in which approved medical schools are located, was 6,560, while in the second group, states which have no approved four year medical school within their boundary, 939 were examined.

In table 8 the figures pertaining to failures before medical licensing boards are subdivided by the number of candidates who were licensed after previous failures. The figures are presented in three categories—approved medical schools in the United States and Canada, foreign faculties of medicine and unapproved institutions. Within these groups there are classifications indicating the number who were licensed after failing a state board examination once and after two or more failures. It can also be noted whether the single or multiple failures have been in the state where licensed or elsewhere. The total number of candidates examined in 1948 and licensed or granted licenses by reciprocity or endorsement of credentials is shown and also the total number of failures in all groups.

There were 13,551 licenses to practice medicine issued during the calendar year 1948. Five hundred and thirty physicians represented in the 13,551 licenses issued had previously been unsuccessful before a licensing board. From the approved schools 245 had previ-

ously failed a state board examination. Eighty-five had one failure in the state in which they were licensed, while 111 were licensed after one failure in another state. Forty-nine received licenses after more than one failure.

In the group of foreign medical faculties, 196 graduates were licensed after previous failure. Also, 89 graduates of unapproved institutions were registered

included in table 9. Florida and Hawaii have not established reciprocal agreements. Provisions for reciprocal licensure have been provided in Idaho by the 1949 legislature and will become effective July 1, 1949. Idaho and Hawaii will endorse certificates of the National Board of Medical Examiners. Florida is the only state which requires a written examination of all applicants for licensure. Those desiring licenses by

after failing previously. Among those with multiple failures in these two groups were several that had more than five and even ten unsuccessful tests before attaining licensure.

In five states all physicians licensed last year had no failures in a state medical examination before being registered.

Registration by Reciprocity and Endorsement

A summary of the reciprocity and endorsement policies pertaining to medical licensure in effect in the United States, Alaska, Hawaii and Puerto Rico are

reciprocity and endorsement in seventeen states, the District of Columbia and Alaska are required to obtain a certificate from the state board of examiners in the basic sciences before being eligible for medical licensure.

Thirty states and Alaska have definite reciprocal agreements with specific states. Twenty-nine boards, including twelve which have specific reciprocity agreements, and Puerto Rico, are given discretionary powers under the medical practice act. The latter licensing boards will register physicians who present credentials which correspond with those required by their respec-

tive states in the year issued. The states in which physicians certified by the National Board of Medical Examiners are accepted for licensure on the basis of the board's certificate are also indicated.

faculties of medicine on a reciprocal basis. Other requirements or exemptions are indicated by footnotes.

This chart will be available in reprint form. It has proved to be of material assistance to physicians con-

This summary should be supplemented by direct communication with the

Some states have additional requirements for graduates of schools outside the United States and Canada.

+, indicates reciprocal or endorsement relationships have been established; .. indicates no reciprocal or endorsement relationships have been established. (See column—"At the discretion of the board.")

1. 1st P, first papers required; @, in citizenship column indicates full citizenship required, in other columns it implies a requirement.

2. In most cases there is a small additional recording or registration fee.

3. Year of practice after internship required.

4. Internship accepted in lieu of one year's practice.

5. Professional practice required.

6. All applicants must be graduates of a medical school approved by the American Medical Association.

7. Just preceding

8. No basic science must be within the state.

9. Basic science by reciprocity or examination in addition to basic science subjects of National Board.

10. Canadian citizens are required to file first papers.

12. Oral examination required when original license is ten or more years old.

13. Applicant must have resided in the state used as basis of application for one year after date on said certificate, or show two years of licensed practice in some other state.

14. Oral examination required.

16. Actual practice for a period of three years immediately preceding date of application.

17. Practical, clinical examination required.

18. Foreign graduates only.

19. Regular and Homeopathic boards.

20. Reciprocity is extended to all states which accept Oregon licentiates on reciprocity basis.

22. Fee same as applicant's state charges if more than \$50.

23. Oral examination required if applicant's state requires it.

Additional requisites, such as professional practice, oral examination and internship, are recorded, as is also the fee for a license without written examination. Citizenship prerequisites are mentioned. In some states physicians of Canadian birth are exempt from the citizenship requirement. This is indicated by a footnote. Few states will accept graduates of foreign

templating locating in another state. The data recorded are intended to be merely a summary of licensure policies. A physician using this chart for reciprocity purposes should supplement the information contained therein by direct communication with the executive officer of the licensing board of the state in which he is interested.

In table 10 are presented data pertaining to the credentials accepted as the basis for licenses granted without written examination in 1948. There were 7,584 so registered on the basis of licenses issued by other reciprocity or endorsement has been steadily increasing. In the last three years, however, the figures have more than doubled those of any previous year.

The greatest number of licenses issued by this

secretary of the licensing board of the state in which the physician is interested.

24. If the applicant passes the examination in the state from which he transfers after the completion of his internship, no practice is required.

25. License in state with which Louisiana reciprocates required.

26. Internship accepted—considered equivalent to two years' practice.

27. Fee \$25.

28. Fee for license on basis of National Board certificate, \$25.

29. A two year internship is accepted.

30. Diplomates of National Board not required to have been in practice for three years.

31. Same as required of Utah candidates applying for licensure.

32. Clinical examination required.

33. Reciprocity applicants only.

34. Supplemental examination required in certain cases when accepting the examination of a state with whom reciprocal relations have not been established.

35. May be licensed after a special (written) supplemental examination.

36. Fee \$30.

37. For matriculants after Oct. 15, 1937.

38. Fee, \$20.

39. Fee, \$15.

40. Permanent license withheld until completion of citizenship.

41. Graduates of foreign medical schools effective Sept. 15, 1935. Canadian schools exempted effective Sept. 19, 1939.

42. Graduates of foreign medical schools are not accepted.

43. Graduates of foreign medical schools must have fulfilled all requirements of California prior to admittance to examination for any certificate used as basis of application to California.

44. Not applicable to citizens of Canada.

45. Not required if country in which applicant is licensed will admit to practice citizens of the United States licensed to practice in some state or on proof of requirements similar to those required by California of graduates of foreign medical schools.

46. Not required for licensure by reciprocity.

47. Reciprocal licensure provisions provided by 1949 Legislature, effective July 1, 1949.

states, the District of Columbia, the territories or possessions, foreign countries, the certificate of the National Board of Medical Examiners, also the government services and special exemption. The number of licenses issued by this method again exceeded any pre-war year, although it was 98 fewer than the number so issued in 1947. The number of licenses granted by method was in California, where 1,270 were registered New York issued 959. Two other states endorsed more than 300 candidates, namely Massachusetts, 392, and Texas, 371. Seven states endorsed more than 200. The largest number of candidates presenting the same type of credentials were the 2,474 physicians certified by the National Board of Medical Examiners, who were

TABLE 10.—Candidates Licensed by Reciprocity and Endorsement of Credentials, 1948

[illegible]

registered in 42 states, the District of Columbia and Hawaii. Of these, 703 were certified in New York, 295 in Massachusetts and 222 in California.

There were 496 licenses issued in Illinois and 365 in New York presented to other states for endorsement purposes. The greatest number licensed in any one state presenting a like state license were 210 Illinois licentiates who secured licenses in California. Only 167 California licenses were presented for reciprocal registration last year, while that state licensed on credentials 1,270 physicians from other states. In contrast with California, 496 licentiates of Illinois were licensed in other states, while it endorsed 234 physicians. No physician holding a New Mexico license applied for registration in another state during the year, and only 2 each from Idaho and Wyoming did so.

One hundred and thirty-two medical officers of one of the government services received licenses by endorsement of their military credentials in eight states. Eleven physicians were licensed in three states on the basis of a license issued in one of the territories or possessions of the United States, 44 on the basis of Canadian or foreign licenses and 18 by special exemption.

In table 11 are recorded the numbers from individual schools represented by the 7,584 reciprocity licentiates. Every approved medical school in the United States and Canada had graduates licensed without written examination in 1948. Three hundred and five graduates of Harvard Medical School were so registered. There were more than 200 graduates of four other schools who sought such licensure. This table reflects the movement of physicians to states other than the one in which they obtained their professional training.

One hundred and nineteen graduates of foreign medical schools obtained endorsement of state licenses in eighteen states, the District of Columbia and Puerto Rico, and 136 graduates of schools no longer in operation were registered by thirty-five boards. Sixty graduates of unapproved medical schools or schools of osteopathy secured similar licenses in thirteen states.

Licentiates Representing Additions to the Medical Profession

Licentiates of 1948 who received their first license to practice medicine and surgery during the year and therefore represent additions to the medical profession in the United States, Alaska, Hawaii and Puerto Rico are shown in table 12 (page 310). The figures in this compilation represent candidates examined in 1948 and licensed, some who were examined in previous years but whose licenses were withheld pending completion of a required internship, citizenship and other technicalities and issued in 1948, and those without a state license who were during the year certified on the basis of the examinations of the National Board of Medical Examiners, government services, Canadian and foreign credentials. The majority represent recent graduates.

There were 6,597 additions to the medical profession in 1948 in the United States, Alaska, Hawaii and Puerto Rico. By reference to table 1 it can be noted that 13,551 licenses were issued during the year, indicating that 6,954 had previously been licensed. The number of physicians removed by death in the United States, territories and possessions was 3,230.¹ Thus the physician population in the United States was increased by 3,367.

It may be assumed that the 1948 figure represents many medical officers returning to the private practice of medicine on completion of their graduate training, which was curtailed by their entry into military service.

Analyzing table 12, it can be noted that New York had the greatest number of first licentiates, 999. California was second, with 505. Two states, Illinois and Pennsylvania, each added 460. Comparison with 1947 figures shows increases in twenty-two states. Of the smaller states in terms of population increases over 1947 figures² were noted in Nevada, New Hampshire, New Mexico, North Dakota, Utah, Vermont and West Virginia, which suggests a measure of improvement in the distribution of physicians and likewise of medical care.

The 6,597 licentiates constituting additions to the medical profession in the last calendar year represented 4,903 who secured their licenses by examination and 1,694 by endorsement of credentials. The latter were mainly physicians certified by the National Board of Medical Examiners.

Increases in the physician population arranged in nine geographic divisions in the United States are shown in table 13. The Middle Atlantic and East North Central group of states added the greatest number, 1,600 and 1,295, respectively. More than 500 were added in five other groups—New England 524, West North Central 650, South Atlantic 830, West South Central 555 and Pacific states 600. The East South Central states added 312, the Mountain states 158 and the territories and possessions 139.

In the fourteen years from 1935 to 1948, inclusive, there were 87,134 physicians added to the medical profession in the United States. Figures for each year during this period are presented in table 14 (page 311). Of the 87,134 additions, 76,628 were licensed after a successful written examination and 10,506 by reciprocity or endorsement of credentials. In the same period 143,684 licenses were issued, 88,097 by examination and 55,587 by endorsement of credentials. These figures indicate that 56,550 licenses were obtained by physicians who had previously been licensed to practice medicine and 87,134 were actual additions to the medical profession.

Estimated figures indicate that on April 15, 1949, the total number of physicians in continental United States was 202,516, of whom 151,888 were estimated as in private practice. The figure 202,516 includes licensed physicians engaged in full time research, teaching and administration. It also includes physicians who have retired, interns and residents in hospitals, and those in the government services.

Licensure Under the Accelerated Program

During 1947-1948 the medical school calendars of three schools in the United States and one in Canada were somewhat irregular as a result of the wartime accelerated program. One school plans to continue the accelerated program. The majority of physicians who obtained their professional education under this plan have experienced no difficulty in obtaining licensure.

Premedical Training Requirement of Licensing Boards

The minimum requirement of the Council on Medical Education and Hospitals for admission to approved medical schools since 1918 has been two years of college training. In 1938 the Council recommended that at least three years of college training be required

1. J. A. M. A. 139:4 (Jan. 22) 1949.

2. J. A. M. A. 137:7 (June 12) 1948.

of all candidates for admission. With the exception of California, the state licensing boards (table 15), by statute in the majority of instances, require that an applicant for licensure must present evidence of having completed two years of college. For the session 1947-1948, seventy-five approved schools in the United States and three in Canada required for admission three or more years of college work.

Required Internship

The medical schools requiring an internship for the M.D. degree are shown in table 16. Six schools in the United States and four in Canada have this requirement.

The internship is a requirement for licensure by the state examining boards of twenty-four states, the District of Columbia, Alaska, the Canal Zone, Hawaii, Puerto Rico and the Virgin Islands. Fifteen boards require the internship to be a rotating service. Puerto Rico has a two year rotating internship requirement. The boards enforcing this regulation are listed in table 17. In addition, some states require the internship for graduates of medical faculties abroad and from reciprocity or endorsement applicants.

The hospitals approved for intern training by the Council on Medical Education and Hospitals of the American Medical Association are generally acceptable in those states requiring an internship for licensure. The current list of approved internships was published in the May 14, 1949, issue of THE JOURNAL.

Licensure Requirements for Interns and Residents

In the majority of states, physicians serving internships are not required to be licensed in the state in which the hospital where they are interning is located. The legal requirements for physicians engaged in residency training varies. Some states do not enforce a licensure regulation. A number of states, however, consider that residents are practicing medicine and require that such persons possess a license in the state. In some instances the boards permit a physician to engage in internship or residency training for a specified period before obtaining licensure. The specifications of each state are given in table 18.

Professional Educational Requirements of Licensing Boards

The medical practice acts or board rulings of several state medical boards state in terms of hours, weeks or months the length of the medical school academic year, as well as the total time in hours, weeks or months which must be spent in medical school. In other states the law or ruling reads that the professional educational requirement accepted for approval by the Council on Medical Education and Hospitals of the American Medical Association and the Association of American Medical Colleges is the regulation for licensure. Table 19 outlines the requirement of each state in this respect. This table does not record the internship which is a requirement for licensure by thirty boards. (See table 17.)

Schedule of Written Examination Dates and
Reciprocity Meetings

The current schedules of state licensing boards for examination for medical licensure and meetings for the issuance of licenses by reciprocity and/or endorsement are given in table 20. Examination dates and reciprocity meetings have in recent years been scheduled by many states at more frequent intervals to assist physicians to commence the practice of medicine without delay. This is particularly true with regard to the issuance of licenses without examination. The increase in the number of applicants for licensure in the last three years has added greatly to the duties and responsibilities of licensing boards, and they are to be commended for the excellent spirit in which they have attempted to meet the demand. In some states temporary permits are granted enabling physicians to begin the practice of medicine immediately.

Licensure on Government Credentials

In most of the states no provision is made in the medical practice act for the acceptance of government credentials as a basis for licensure without examination. Six licensing boards, however, will issue a license to a physician who has passed an examination for admission to the medical corps of the United States Army, Navy or Public Health Service. These states are California, Illinois, Texas, Utah, Virginia and Wisconsin. Legal residents of Pennsylvania who were qualified to take

the state board examination but were prevented from doing so by reason of enlistment or induction into the military or naval forces of the United States are licensed without examination in that state.

Temporary Permits

The licensing boards of fifteen states and Puerto Rico provide for the issuance of temporary permits. These states, the length of validity of the permit and the number of permits granted during the last calendar year are shown in table 21. Florida, Nevada, North Carolina, Utah and Washington discontinued this service in 1948, while Alaska and Idaho were added to the list. In Idaho the regulation will become effective July 1, 1949. In Nebraska and Virginia, temporary permits are available for reciprocity applicants only, while in Puerto Rico it applies to those in government positions.

Annual Registration

Thirty-one states, the District of Columbia, Alaska and Hawaii require physicians to register their licenses annually or biennially. In table 22 are listed the licensing boards which have such a requirement and the fee charged. Some of these boards require such registration whether or not physicians reside in the state. The fee ranges from \$1 to \$10. Six states have a non-resident fee. Missouri and New York require biennial registration. Annual registration of medical licenses will be effective in West Virginia on July 1, 1949.

Candidates Examined, 1944-1948

The numbers of candidates examined in the various states, territories and possessions in five years, 1944 to 1948, inclusive, are recorded in table 23. For each year there is recorded the number who passed and failed licensing examinations. Totals for the five year period and the percentage of candidates who failed are also given.

In this five year period 34,078 examinations were given. Of these, 30,461 were successful tests and 3,617, or 10.6 per cent, resulted in failures. New York gave the greatest number of examinations, 4,052. More than

Totals.....	4,903	1,694	6,597

2,000 examinations were also given in California, Illinois and Pennsylvania, and more than 1,000 candidates were examined by the licensing boards of Florida, Louisiana, Minnesota, Missouri, Ohio and Texas.

Massachusetts had the highest percentage of failures owing to the fact that, by law, the licensing board admitted to its examinations the graduates of unapproved medical schools and graduates of schools of osteopathy, many of whom repeatedly fail. The number failing in this state in 1948 was the lowest in the five year period and will probably still further decrease because of the closure of schools whose graduates constituted a great majority of the failures. Furthermore, the State Approving Authority has ruled that students matriculating after Jan. 1, 1941 in institutions not meeting the standards of this authority will not be eligible for licensure.

New York had a failure percentage in the five year period of 45.6. This state examines a considerable number of foreign trained physicians, many of whom are not successful in the first examination. Regula-

Effective September 1947.

1. Physician registered with state board may serve as intern not to exceed two years without licensure.
2. May commence residency before licensure.
3. Required by some hospitals.
4. Registration with state board required.
5. May have service of two years without licensure.
6. May have service of three years without licensure.

Registration of Physicians, 1904-1948

A tabulation of totals and percentages for forty-five years from 1904 to 1948, inclusive, is included in table 24. This study contains figures pertaining to the num-

ber of physicians registered by written examination and by reciprocity and/or endorsement, of credentials. There is also shown the numbers who failed annually in forty-five years, as well as the percentage of failures each year and, lastly, the total annual registration. Reviewing the number of physicians registered since 1904 reveals no definite trend in earlier years. In 1918,

practice. In 1943 more physicians were registered than in any previous year.

The number registered in 1946 was almost double the number registered in 1945. Separation from service of a large number of medical officers and their return to private practice in states other than those in which they were licensed accounts in large part for this

* Association of American Medical Colleges and Council on Medical Education and Hospitals of the American Medical Association.
x In columns 5 and 13 implies requirements are those of the two accrediting agencies.

however, there was a decrease of more than 1,200 from the previous year. This decrease was due to the sudden withdrawal of physicians and recent graduates from civilian life during World War I. After 1933 there was an upward trend for a time, followed by a decline in the years 1940 to 1943, inclusive. There was a noticeable increase in 1943 which was the result of the accelerated curriculum and the universal effort on the part of the medical leaders of the country to maintain a steady flow of physicians for both civilian and military

increase. This increase was also evident in 1947 and 1948, although the numbers registered were fewer than in 1946.

In 1904, the first year shown, the percentage of failures was 19.3. This was the era of proprietary medical schools. The percentage of failures gradually dropped each year until 1930, when 5.7 per cent failed. With the migration of European physicians to this country beginning in 1936 and the resultant licensure difficulties, the percentage of failures began to rise,

reaching another peak of 20.7 per cent in 1940. Beginning in 1944 there was a decrease in the numbers of foreign trained physicians and graduates of unapproved medical schools which has resulted in a reduction in the annual percentage of failures as contrasted with previous years.

In analyzing this table it should be remembered that the figures refer to examinations given rather than individuals examined.

Graduates of Approved Schools and Others Registered, 1922-1948

In table 25 the numbers of physicians registered are grouped in two categories, namely, graduates of approved medical schools and others. In the computation of these figures, schools rated as class A and B by the Council on Medical Education and Hospitals of the American Medical Association since 1907 are classified as approved. In the column headed "Others" are included persons who graduated prior to 1907, when the first classification of medical schools was made by the Council, graduates of foreign faculties of medicine, class C graduates, osteopaths given recognition by medical licensing boards, and graduates of schools not approved by the Council. In 1928 the

classification A, B and C by the Council was discontinued and a list of approved medical schools has since been maintained.

In 1948 there were 13,424 candidates registered, of whom 12,721 or 94.8 per cent represented graduates of approved schools and 703 (5.2 per cent) were in the

second group. In the twenty-seven year period 236,527 were registered, including 211,722 approved graduates, 89.6 per cent, and 24,805 others, 10.4 per cent. For the period shown, more than 80 per cent of those licensed have been in the approved group. Until the influx of foreign graduates in 1936 and concessions made for graduates of unapproved schools and schools of osteopathy, those in the second group were fewer than 1,000. The number registered in 1948 was 315 fewer than in 1947.

Graduates of Unapproved Schools Registered, 1943-1948

Recorded in table 26 are data regarding graduates of institutions which do not measure up to the minimal essentials of an acceptable medical school as outlined by the House of Delegates of the American Medical Association and administered by the Council on Medical Education and Hospitals. This table shows the number

registered as medical licentiates in the United States and Hawaii by written examination and by reciprocity and/or endorsement of credentials in the past six years, 1943 to 1948 inclusive. Figures are given separately for these two groups. In the six years shown, nineteen states and Hawaii registered 1,176 by examination and

23 by endorsement. In 1948, there were 176 registered, 173 by examination and 3 without written examination in ten states, Arizona, Florida, Illinois, Massachusetts, Mississippi, Nebraska, New York, Ohio, Virginia and Washington.

Illinois, which accepted for licensure the graduates of one school not approved by the Council until late in 1948, New York and Florida, which have made certain concessions, and Massachusetts licensed the largest number of graduates of unapproved medical

schools. In the latter state, the institutions referred to in the table were not granted approval by the State Approving Authority. Matriculants after Jan. 1, 1941 are not eligible for licensure in Massachusetts.

Graduates of Schools of Osteopathy Registered by Medical Examining Boards, 1943-1948

In sixteen states and the District of Columbia during the last six years (1943-1948) graduates of schools of osteopathy have been granted the privilege of practicing medicine or surgery or both by the medical examining board. The states which have registered such candidates and the numbers so registered are given in table 27. There have been 1,278 such persons registered

since 1943, 975 by examination and 303 without examination. In 1948 there were 213 so registered, 102 by examination and 111 by reciprocity by eleven medical

licensing boards, Colorado, District of Columbia, Massachusetts, New Hampshire, New Jersey, New York, Ohio, Oregon, Texas, Virginia and Wisconsin.

Following is a summary of the situation in the sixteen states and the District of Columbia providing for the licensing of osteopaths by the medical examining board.

In 1947, Alabama registered a graduate of a school of mechanotherapy.

In Colorado an osteopath receives a license to practice medicine. In Connecticut any registered osteopath may practice either medicine or surgery or both, as the case may be, if he passes a satisfactory examination before the medical examining board. In Delaware osteopaths are licensed as "osteopathic physicians." In the District of Columbia osteopaths are granted the right to practice surgery. In Indiana the licenses issued to osteopaths under a 1945 amendment to the medical practice act authorize the holders to practice medicine and surgery. Licentiates in osteopathy prior to 1945 have now been authorized to practice osteopathy, surgery and obstetrics. In Massachusetts the medical practice act, by definition, includes osteopathy in the practice of medicine and does not differentiate the type of license issued to an osteopathic applicant. According to a law passed in Nebraska in 1943, "any person now licensed to practice osteopathy may, if application was made prior to July 1, 1948 and upon payment of the prescribed fee, take the first regular examination given after the application is made before the Board of Examiners in Medicine. . . . If successful, he or she shall receive a license to practice medicine and surgery in the state." In New Hampshire osteopaths are granted the right to practice medicine and surgery.

New Jersey provides that osteopaths licensed prior to November 1, 1941 who furnish proof prior to that date of having served for a period of two years as an intern or resident surgeon in an osteopathic or medical hospital approved by the board of medical examiners, of having completed a postgraduate course of two years in a college of osteopathy or medicine approved by the board or of having had at least three years of practice in a hospital approved by the board can be admitted to an examination in pharmacology, therapeutics and surgery and, if successful, can obtain a license to practice medicine and surgery. Since 1941 all osteopathic applicants who have met the requirements of the medi-

cal practice act have been licensed to practice medicine and surgery.

In New York a law approved April 10, 1946 provides that any osteopathic licentiate who had obtained the additional right to use instruments for minor surgical procedures and to use anesthetics, antiseptics, narcotics and biologic products or any applicant who has met or shall meet all the preliminary and professional requirements as required as of Sept. 1, 1936 and has satisfactorily passed or shall satisfactorily pass the regular medical licensing examination shall be granted the right to practice medicine without limitation as defined by the statutes of the State of New York.

A law passed in Ohio in 1943 gives osteopaths who obtain their licenses under that act the right to practice osteopathic medicine and surgery. In Oregon they are granted the right to practice "in the subjects" covered by the examination, which includes surgery. The medical practice act of Texas provides for the issuing of a license to practice medicine only, and osteopaths are issued licenses unrestricted in scope. In Virginia osteopaths may obtain the right to use drugs and perform surgery with the use of instruments if they satisfy the board of medical examiners that they are qualified to do so. Wisconsin grants osteopaths the privilege of practicing surgery, and in Wyoming the statutes contain no specific provision for the licensing of osteopaths. The medical practice act of the latter state provides that the certificate issued to all applicants "shall be deemed licenses to practice medicine in all branches in which the applicant has taken examination in the state."

Licensure of Foreign Trained Physicians

The Council on Medical Education and Hospitals does not grade or classify medical schools outside the United States and Canada. It does not attempt to evaluate institutions which it is not in a position to visit to determine whether they meet the minimal essen-

tials of an acceptable medical school as outlined by the Council. This was true even before the war.

For a period of twelve years beginning in 1926 the credentials of physicians coming from abroad were verified by the Council through official correspondence with the medical schools directly or through the diplomatic services. Prior to the onset of the war in Europe it was necessary to discontinue this effort, and on the licensing boards rests the responsibility of evaluating

the credentials presented by these graduates. In the 1942 edition of the American Medical Directory a symbol in the biographic data of foreign graduates indicates when the information given is the licensing board's

the problem of evaluation of foreign credentials submitted by physicians and students from foreign medical schools. This committee has held several meetings and on March 25, 1949 stated³ that the

x. Implies Yes.

* Refer to chart "Reciprocity and Endorsement Policies" for further data.

1. Certificate of National Board of Medical Examiners required.

2. (a) Citizenship waived if country in which applicant is licensed will admit to licensure citizens of the United States. (b) Acceptable for reciprocal registration if license submitted was granted on same standards as in effect in California on the same date and on completion of an oral, clinical and written examination. (c) Rotating internship in approved hospital in United States or completion of senior year in approved medical school in United States.

3. Effective July 1, 1948, physicians who have graduated from medical schools located outside of the United States, Canada or the British Isles subsequent to Jan. 1, 1940 not eligible.

4. Residence of one year in Delaware required.

5. (a) Acceptable for reciprocal registration if similar privileges are accorded licentiates of District of Columbia by licensing agency or jurisdiction from which the applicant comes. (b) Regulations cited refer also to graduates of Canadian schools.

6. Senior year in an approved medical school in the United States or Canada, possess the degree of Master of Public Health from an acceptable school, or satisfactorily complete a one year's assistant residency, residency or fellowship in an approved hospital in the United States accepted as further training.

7. Further training—Completion of senior year in approved medical school in the United States.

8. Further training—Internship or one year in medical school in the United States.

9. (a) Applicant must be licensed to practice medicine and surgery in country in which school of graduation is located, otherwise required to complete senior year in approved medical school in United States. (b) In lieu of internship, certificate from three graduates of the applicant's medical school licensed to practice medicine in United States accepted.

record of the credential accepted as meeting the educational qualifications for licensure. The absence of the symbol may be interpreted to indicate that official verification is on file in the office of the Council.

A committee composed of representatives of nineteen interested organizations has been formed to consider

10. (a) Applicant must be licensed to practice medicine and surgery in country in which school of graduation is located, otherwise required to complete senior year in approved medical school in United States. (b) No applications accepted from countries other than England (certain schools), Ireland, Scotland and Australia.

11. These requirements apply also to graduates of medical schools of Canada.

12. Applicants considered individually.

13. At the discretion of the licensing board.

14. Diplomates of National Board of Medical Examiners eligible on reciprocity basis.

15. (a) Internship completed in foreign countries after July 1, 1934 not acceptable. (b) Matriculants of medical schools of Europe and Asia after Nov. 19, 1941 not accepted. (c) Graduates of medical schools of South American Republics, Mexico and Cuba not accepted.

16. Matriculants after Jan. 1, 1940 not accepted.

17. License to practice medicine and surgery in country in which school of graduation is located, otherwise required to complete senior year in approved medical school in United States.

18. Applicants limited to university medical schools of Great Britain.

19. Medical education completed in foreign medical schools since 1941 not acceptable.

20. (a) Matriculants in foreign medical faculties subsequent to Jan. 1, 1949 not acceptable. (b) Applicant must be licensed to practice medicine and surgery in country in which school of graduation is located.

21. European graduates after 1939 limited to English speaking schools.

22. Enabling legislation passed in 1949 permits licensure of graduates of foreign medical faculties under regulation to be set up by new Board of Medical and Osteopathic Examiners which relieves Board of Health of medical licensing duties.

various agencies concerned should unite their resources and devise a satisfactory method for securing reliable information concerning foreign medical schools at the earliest possible date. When such information is obtained, it should be possible for the accrediting agen-

cies to prepare a list of foreign medical schools whose graduates may be considered to have training comparable to that offered by medical schools in the United States.

The present requirements for candidates seeking medical licensure in the United States, Alaska, Hawaii, Puerto Rico and the Virgin Islands on the basis of credentials obtained in countries other than the United States and Canada are given in table 28. Twenty-one states and the Virgin Islands reported that the holders of such credentials are not eligible for licensure. Seventeen states, Alaska, Hawaii and Puerto Rico require full citizenship and eight states require naturalization papers as a condition precedent to taking the examination for licensure. The District of Columbia, Indiana and Michigan make no reference to citizenship. In some states the recognition or nonrecognition of foreign-trained physicians is by board ruling; in others the provision is by statute. Nine states and Alaska which will admit foreign graduates require a certificate from the state board of examiners in the basic sciences.

Totals.....	15,156	7,855	48.1

Sixteen states, the District of Columbia, Alaska, Hawaii and Puerto Rico require that the foreign-trained physician serve an internship in a hospital in the United States before examination for licensure. Additional qualifications are given in footnotes of the table.

Figures relating to foreign-trained physicians examined for medical licensure in the United States in 1948 are presented in table 30. These statistics represent both American and foreign-born physicians educated in countries other than the United States and Canada. Graduates of 85 faculties of medicine and 3 licensing corporations of eighteen European countries and 20 schools of thirteen other countries were examined. The number examined totaled 636 and were tested in twenty-seven states, the District of Columbia and Puerto Rico. The number who were successful was 308; failures numbered 328 or 51.5 per cent. Graduates of the University of Vienna represented the largest group from any one school, 76, who were examined in ten states, with a failure percentage of 48.7. Fewer than 31 of the graduates of any other school were tested.

The greatest number of foreign-trained physicians examined for licensure last year by any one state was

417 in New York, of whom 178 passed and 239 (57.3 per cent) failed. No other state tested more than 60 of these physicians.

Table 29 records the number of foreign-trained physicians examined for medical licensure in the United

Virgin Islands	Dr. Christian R. Moorehead, Charlotte Amalie.

States in nineteen years (1930 to 1948). In this period 15,156 were examined, of whom 7,855 passed and 48.1 per cent failed. At no time in this nineteen year period did fewer than 30.7 per cent fail. In 1936 the number of foreign-trained physicians began to increase, and by 1940 there were over three times as many tested as in 1936. Since 1940 there have been annual decreases, but the annual total still is greater than the 1936 figures

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

A basic science law provides for the establishment of a board of examiners and requires that each person who desires to practice the healing arts appear before that board and demonstrate his knowledge of the basic sciences. Such boards are distinct from licensing boards. A certificate of proficiency in the basic sciences does not authorize the possessor to practice the healing art; it enables him only to apply for licensure.

A basic science certificate is a prerequisite for licensure in seventeen states, the District of Columbia and the Territory of Alaska. The states comprising this group, together with the year of enactment of their basic science law, are recorded in table 31.

The subjects in which examinations are given are specified in the law. Table 32 lists the states and the subjects in which examination is required. These subjects are not uniform, although all boards examine in anatomy, pathology and physiology, seventeen examine in chemistry, fifteen in bacteriology, nine in hygiene, two in diagnosis and one in public health. The laws in some states provide for certification without examination by the endorsement of a basic science certificate issued in another state and the acceptance of successful

examinations in the required subjects given by a state licensing board or the National Board of Medical Examiners.

The results of examinations given and the number of certificates issued on the basis of reciprocity or endorsement as reported by the basic science boards are shown in tables 33 and 34. The laws do not specify that a candidate reveal his school of practice. The lists submitted by the respective boards, however, have been checked with the biographic records of physicians and medical students maintained by the American Medical Association and with various directories. In this way it has been possible to determine the profession of the majority of candidates. By this means the figures have been tabulated in four groups; namely, physicians and medical students, osteopaths, chiropractors and unclassified applicants. The latter category include those for whom it was not possible to determine the profession represented. In Rhode Island, however, the unclassified group represent doctors of dentistry. It is probable that others in this unclassified group include osteopaths, chiropractors and naturopaths who have not been identified by the reference material available.

The nineteen boards in operation in 1948 examined 3,947 candidates. The numbers examined in the four groups named are shown in table 33. Physicians and medical students represent the greatest number examined. There were 3,000 in this group. There were also examined 173 osteopaths, 216 chiropractors and

438 in the unclassified group. Of all applicants 23 per cent failed, of the physicians and medical students examined 13.3 per cent failed, osteopaths 38.7 per cent, chiropractors 65.2 per cent and unclassified 41.3 per cent. The basic science board of Florida examined the greatest number, 609, representing 533 physicians and

* Nature of practice undeterminable since names of failures not supplied.

† Figures in unclassified column refer to doctors of dentistry.

76 others with 24.4 per cent failures. Iowa, Michigan and Minnesota examined more than 300. The percentage of failures in these states was 45.4, 16.8 and 20.8, respectively. New Mexico reported no failures. The percentage of failures for physicians and medical students seems rather high, particularly when compared with the extent of failures before the state examining boards of the respective states.

It is the policy of the Arizona and Minnesota boards in reporting results of its examinations to omit the names of applicants who fail examinations. The number who fail are therefore recorded only in the total column.

Physicians or medical students were examined in all states, osteopaths in twelve states and chiropractors by ten boards.

Twelve boards granted basic science certificates without examination, by reciprocity, endorsement, waiver or exemption. There were 1,418 certificates awarded by this method in 1948. By both examination and endorsement, 4,456 certificates of proficiency were issued. The number of successful candidates in these two groups are recorded for each state in table 34. Among the successful candidates were 3,670 physicians or medical students, 218 osteopaths, 137 chiropractors and 431 others.

Table 35 records the number of candidates examined and the number certified without examination by basic science boards in twenty-two years, 1927 to 1948 inclusive. In 1927, when five boards were functioning, there were 305 physicians examined, of whom 8.5 per cent failed, and 22 others, of whom 31.8 per cent failed. In 1948 there were examined 3,000 physicians with 13.3 per cent failures and 827 others, of whom 47.1 per cent failed.

In twenty-two years, 31,566 physicians and medical students were examined, of whom 26,946 were successful in their examinations. In the same period 5,080 other practitioners were tested and 2,627 were successful. By both examination and endorsement there were 34,100 physicians or medical students issued certificates in twenty-two years and 4,247 certificates were issued to other practitioners.

Basic science laws have been enacted in order that all who seek to care for sick and injured persons can

for basic science registration is done in many states by nonmedical examiners.

The basic science boards now operating have formed an American Association of Basic Science Boards which is in position to provide information to states contem-

be tested to determine whether they possess a reasonable knowledge of the sciences fundamental to the healing art. The results of the examinations demonstrate that, in general, practitioners other than physicians are not adequately equipped in the fundamentals of medical care. This is particularly significant, since the testing

plating basic science legislation. Procedures are under consideration to facilitate reciprocity arrangements. At present, certification by reciprocity is difficult because of differences in the laws of the various states.

The present executive officer of each of the nineteen basic science boards is as follows:

OFFICIALS OF BASIC SCIENCE BOARDS

Arizona—Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

Arkansas—Mr. L. E. Gebauer, 1002 Donaghey Building, Little Rock.

Colorado—Esther B. Starks, D.O., 1459 Ogden Street, Denver.

Connecticut—Mr. C. M. Bakewell, 110 Whitney Avenue, New Haven.

District of Columbia—Dr. G. C. Ruhland, 4130 East Municipal Building, Washington.

Florida—Mr. M. W. Emmel, University of Florida, Gainesville.

Iowa—Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan—Miss Eloise LeBeau, 101 North Walnut Street, Lansing.

Minnesota—Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis 14.

Nebraska—Mr. Oscar F. Humble, 1009 State Capitol Building, Lincoln 9.

New Mexico—Miss Marguerite Kilkenny, 110 West Houghton Street, Santa Fe.

Oklahoma—Dr. Frank C. Gallagher, 813 Braniff Building, Oklahoma City.

Oregon—Dr. C. D. Byrne, University of Oregon, Eugene.

Rhode Island—Mr. Thomas B. Casey, 366 State Office Building, Providence.

South Dakota—Dr. G. M. Evans, 310 East 15th Street, Yankton.

Tennessee—Dr. O. W. Hyman, 874 Union Avenue, Memphis.

Washington—Mr. Edward C. Dohm, Olympia.

Wisconsin—Mr. William H. Barber, Watson and Scott Streets, Ripon.

Alaska—Dr. C. Earl Albrecht, Box 1931, Juneau.

NATIONAL BOARD OF MEDICAL EXAMINERS

The certificate of the National Board of Medical Examiners is accepted as an adequate qualification for registration by the licensing boards of all the forty-eight states except Florida, Montana and Wisconsin. It is also recognized by the District of Columbia, the territories of Alaska, Hawaii and Puerto Rico and the Canal Zone.

The licensing board of Louisiana exempts diplomates of the National Board from the state examination if they have also been licensed in a state with which Louisiana reciprocates. Additional examinations are required by some licensing boards. These are oral examinations in Hawaii, Illinois, Maine, Rhode Island and Wyoming and a brief supplemental written examination in Michigan.

The boards of examiners in the basic sciences of Alaska, Connecticut, Iowa, Minnesota, Oklahoma, Tennessee and the District of Columbia honor the examination of the National Board and give a qualifying certificate to its diplomates without further examination. The basic science board in Nebraska accepts the board's examinations in most instances after reviewing the answer papers.

Diplomates of the National Board are admitted to the final examination of the Examining Board in England, of the Triple Qualification Board of Scotland and of the Conjoint Board in Ireland. The National Board admits directly to Parts II and III of its examinations the diplomates of these boards provided they hold a degree in medicine from an acceptable university. Diplomates may also be admitted without further examination to the Mayo Foundation for Medical Education and Research provided they possess the other necessary qualifications.

The states, territories and possessions which will endorse the certificate of the National Board are recorded in table 36.

The almost universal recognition of the examinations of the National Board is evidenced by the acceptance of the board's examinations by many schools as part of their own examination and promotion procedures. At some of the schools the students are required to pass part I at the end of the second year and part II at

the end of the fourth year. Other schools require only that part II be passed at the end of the fourth year. In addition, there are a few schools at which those students who voluntarily take and pass the board's examinations, either in part I or part II, are excused from the corresponding final school examinations.

Requirements for admission to the National Board examinations include a standard four year high school course, two years of acceptable college work including English, physics, chemistry, and biology, and medical training satisfactorily completed in approved medical schools in the United States and Canada. Graduates

of the university medical schools of Great Britain and Ireland are admitted to the examinations provided these graduates have been licensed to practice in the country in which the school attended is located.

In the following paragraphs data are presented for the thirtieth consecutive year regarding the examinations conducted and the issuance of certificates by the National Board.

The first examination was given in October 1916. From that date and up to and including a test given in June 1921, eleven examinations were given and 268 candidates were certified. The results of each examination during this period are given in table 37.

Since 1922 the examination of the National Board has been divided into three parts, which must be taken and completed in the following sequence: part I, consisting of a written examination in the basic sciences; part II, a written examination in five major clinical subjects, and part III, a clinical and practical examination in six major clinical divisions and their component subjects or subdivisions. Parts I and II are given in approved medical schools throughout the country, while part III is given under the direction of local subsidiary boards in twenty-five centers at times sufficiently frequent to accommodate all eligible candidates.

The tables that are hereinafter presented enumerate the results of examinations in parts I, II and III for each calendar year since 1922, including those who passed and failed examinations and those certified.

A candidate is eligible for part I who has completed successfully the first two years of work in an approved medical school. An incomplete examination is allowed candidates taking part I at the end of their second medical year in schools whose third year curriculum includes courses in one or two subjects of this part. Examinations in these subjects may be taken after the candidate has completed them in his medical school. They are recorded in these tabulations under the heading "Incomplete Examinations" and are excluded from the calculations referring to the percentage of failures. Divided examinations, which allow the writing of examinations in four subjects at one time and the remaining two at a subsequent examination, is also permitted. Such examinations are not reported until completion of the entire test and are not recorded in the compilations presented.

To be eligible for part II, a candidate must have completed successfully a four year medical school course in an approved medical school and must have passed part I.

A candidate is eligible for part III who has passed parts I and II, received his medical degree and completed an internship of one year in a hospital approved for such training by the American or Canadian medical associations, or has served in a laboratory acceptable to the National Board.

Totals.....	78,136	61,918	10,963	5,255	7.8

Three examinations were given in part I in 1948 and four in part II, while tests in part III were held at various times during the year.

The figures in tables 38 and 39 cover details of each examination given during 1948 and since 1922. The data shown represent examinations conducted rather

than persons examined. The figures include candidates who fail and are reexamined during the same year and those who pass parts I and II in the same year.

In 1948, 3,807 examinations were given in part I; 2,178 passed and 367, 14.4 per cent, failed. There were 1,262 incomplete examinations given. In part II, 1,742 examinations were held; 1,725 passed and 17, or 0.9

per cent, failed. Incomplete examinations are only rarely given in part II. There were none given in 1948.

There have been 45,488 examinations given in part I since 1922 and 23,230 in part II. During this period 27,015 passed part I and 21,921 passed part II. In twenty-seven years there have been 4,537 failures in part I, 14 per cent, and 1,263 in part II, 5.5 per cent. The increasing recognition of the National Board's examinations by medical schools and licensing boards is reflected in the figures presented in these two tables and particularly since 1943. The greatest number of examinations were given in part I in 1944 and in part II in 1943 when medical schools were operating on an accelerated program.

Tests in part III in 1948 totaled 1,715, including 1,700 successful examinations and 15, or 0.9 per cent, failures. Results of examinations given in this part in twenty-seven years are presented in table 40. During this period 19,003 were tested, of whom 18,493 were granted certificates. The percentage of failures in this final examination in twenty-seven years was 2.6. Since 1915, when the board's first examination was given, 18,761 certificates have been awarded. Physicians who

earn the certificate are known as diplomates and are privileged to use the designating initials "D.N.B."

The figures thus far presented represent examinations given. The number of persons tested during any one year is recorded for the twenty-seven year period in table 41. The classification "Passed" or "Failed" in cases in which more than one examination has been taken in a given year was based on the results of the last examination during the year in question. Thus, if in 1948 a candidate passed part I but at a subsequent examination in 1948 he failed part II, he is computed in this tabulation as having failed. These figures reveal that there were 6,389 who took at least one of the tests of the National Board in 1948, as compared with 525 in 1922. The greatest number was evidenced last year. In all 78,136 persons were examined in one or more of the annual examinations in the twenty-seven years shown, of whom 61,918 passed, 10,963 took incomplete examinations and 5,255, or 7.8 per cent, failed.

The 1,700 physicians certified as diplomates in 1948 represented sixty-four medical schools in the United States, four in Canada and nine foreign universities. The school and the number of examinees from each are included in table 42.

Diplomates licensed to practice medicine on the basis of their credentials increased from 2 in 1917 to 2,474 in 1948 (table 43), and 16,694 have been so licensed since the National Board was formed. However, 18,493 have received the certificate of the board.

The membership of the National Board is composed of thirty-two persons, representing the federal services, the Federation of State Medical Boards of the United States, the Association of American Medical Colleges,

MEDICAL LICENSURE

In this issue appears the annual report on the examination and licensure of physicians in the United States and its territories and outlying possessions for the year 1948. The tables and the summaries show conditions at present and indicate trends over many years. During the last year, 13,551 applicants were licensed to practice, 5,967 by examination and 7,584 by endorsement of credentials.

The increment of the medical profession consisting of physicians licensed for the first time was 6,597. During the year 3,230 physicians died. The net gain to the physician population was 3,367. The registration of physicians revealed that 94.8 per cent were graduates of approved medical schools.

The percentage of failures from existing United States schools was 3.3; of graduates of unapproved schools 42.7 per cent failed; graduates of schools of osteopathy admitted to the medical licensure examinations represented 37.8 per cent failures, and 51.5 per cent of foreign-trained physicians failed licensure examinations last year. The total percentage of failures was 10.9.

Data pertaining to examinations given by the boards of examiners in the basic sciences and the National Board of Medical Examiners are included in this study. Osteopaths and chiropractors represented the greatest number of failures before basic science boards. During the year 3,827 certificates were issued by the nineteen basic science boards. The National Board of Medical Examiners, the influence of which has steadily increased since its inception in 1915, issued 1,700 certificates in 1948. All states except Florida, Montana and Wisconsin recognize the certificate of the National Board for licensure, and 2,474 physicians were granted medical licenses on the basis of National Board credentials in 1948.

The publication of these statistics annually is made possible by the conscientious reporting of examination and reciprocity actions by every governmental unit of the United States, its territories and possessions, as well as the basic science boards and the National Board. The cooperation of all these agencies is appreciated and is gratefully acknowledged.

CATHOLIC AGENCIES MAKE STATEMENT ON THE NATIONAL HEALTH PROGRAM

Recently the Bureau of Health and Hospitals of the National Catholic Welfare Conference, the National Conference of Catholic Charities and the Catholic Hospital Association issued a statement entitled "A Voluntary Approach to a National Health Program," under the auspices of the Most Reverend Karl J. Alter, Bishop of Toledo, Episcopal Chairman, Bureau of Health and Hospitals, Social Action Department of the National Catholic Welfare Conference, and Chairman of the Administrative Board of the Catholic Hospital Association of the United States and Canada. In his introduction to the statement, Bishop Alter points out that the agencies concerned "recognize the existence of social responsibility but at the same time they reject the concept of an exclusive state responsibility for the health and well-being of the American people." Bishop Alter says:

They reaffirm their conviction that a partnership between the state and voluntary associations provides the better solution and is more consistent with our democratic processes. Monopoly means control: partnership means freedom.

After rejecting the administration's proposals and after an analysis of the Brookings report and the Ewing statement, the Catholic agencies offer their own constructive program. In their program they recommend establishment of a medical administrator in the Federal Security Agency under the direction of a federal health council. They recommend increase in grants for hospital construction, assistance to medical colleges by paying up to 50 per cent of the salaries of the teaching staff with a ceiling of \$10,000 per person per year. They also recommend grants in aid for the medical schools, loan scholarships to medical students and subsidizing of physicians to encourage service in rural areas. They recommend an appropriation of \$25,000,000 for medical research in medical colleges, assistance to schools of nursing and aid for the development of auxiliary medical personnel. They would meet the costs of prepayment plans for medical care by permitting a reduction of premiums up to \$75 for health insurance from the net income tax of all persons in the lower income brackets, the funds thus lost by the government to be replaced with new taxation. They also recommend appropriation of \$200,000,000 annually to assist the

states in providing health care for the indigent and medically indigent, the money to be used in purchasing insurance and in voluntary plans for those thus classified. Each state would establish a state health insurance agency with the council appointed by the governor to determine policies and approve regulations made by the federal council.

In their conclusion the Catholic agencies call attention to the fact that compulsory governmental insurance programs would by necessity destroy existing voluntary programs. They venture also the opinion that the highly complicated system of assigning, regulating and controlling health services set forth in Senate Bill 5, which is the Wagner-Murray-Dingell bill, would in the judgment of hospital authorities and medical men be practically unmanageable and would so increase demands on existing facilities and personnel that the very weight of the premature demand would necessarily cause deterioration in the quality of the service rendered.

REHABILITATION

The family physician, after seeing a patient through the acute stages of an illness and subsequent convalescence, watched him until his ultimate return to work. The patient, usually stimulated by the daily needs of life on the farm and in the home, was chiefly interested in regaining his former place in his society. As he recuperated, he could make himself useful in many simple tasks. Gradually more difficult and strenuous skills would be regained. The relationship of the family physician to the home was sufficiently direct to permit him to help substantially in the process.

Now, however, and especially in cities, the family physician can no longer help effectively in this rehabilitative phase of medical care. Many people live almost monastically in apartments like cubicles. From the hospital the inmate returns to this cell, where his metabolism can be described in terms like those used by the cytologist in describing the life processes of an erythroblast. Materials to be metabolized are delivered to the service door by the smoothly flowing circulatory system of the metropolis, and the products of this metabolism disappear down chutes, drains and pipes. Of visible motion there is none. The activities of this cell are paradoxically not active, but passive; they consist of looking at papers, listening to radios and watching television. A patient returning to such an environment from a hospital is not stimulated. He has been looking at papers, listening to radios and watching television in the hospital, too. If he gains strength, he may go out to theaters and stadiums, where he will hear and see more of the same thing in the same passive way. Little incentive develops for regaining useful skills. Seldom are there facilities for use by the patient in preparing to resume his former

occupation. The physicians who may have served the patient well during the phases of his recovery in the hospital can do little or nothing for him during the rehabilitative phase.

The consequences of this are stated, with an almost brutal use of statistics, by Howard A. Rusk in an article elsewhere in this issue. Added strains are manifest both in the home, where cramped quarters distress patient and family alike, and in the hospital, where slow recoveries tie up beds. Rusk sees rehabilitation as an essential "third phase" of medical care. The importance of finding places for the handicapped in American industry is made undeniably clear. The roles of physical medicine and of occupational therapy in rehabilitation are seen in a new light.

The interrelations of physical medicine, occupational therapy and rehabilitation are important because of their bearing on the education of young physicians. Hospital residencies may be planned to provide some training in all three fields, and credit should be allotted for such training. The three fields concerned, although they overlap extensively, have in addition certain distinctive areas of their own. The difficulties about residencies have claimed the attention of the Council on Medical Education and Hospitals, and have concerned especially the Council on Physical Medicine. The latter council recently voted to enlarge its scope and to change its name to the Council on Physical Medicine and Rehabilitation; this action should clarify some of the thinking on the subject and will help greatly in dealing with problems like that of residencies. The Board of Trustees of the American Medical Association has voted approval of this change of name.

HUMAN SKIN GRAFTS ON CHICK EMBRYOS

In 1938 Goodpasture¹ and his associates of Vanderbilt University developed a new technic in immunologic and virus research. They found that intact human skin can be successfully grafted on the chorioallantois of the chick embryo. The graft becomes adherent to the membrane and within two to four days becomes vascularized with capillaries carrying chick erythrocytes. The graft is apparently adequately nourished till shortly before hatching, thus giving eight to ten days for its technical use. Attempts to prolong the life of the graft by transfer to a second embryo were almost invariably unsuccessful. Goodpasture inoculated several of his grafts with the virus of herpes simplex, vaccinia and smallpox. The resulting lesions and cellular changes were typical of these infections.

Improvements in this technic are now reported by Blank² and his associates, of the departments of derma-

1. Goodpasture, E. W.; Douglas, B., and Anderson, K.: *J. Exper. Med.* **68**: 891, 1938.

2. Blank, H.; Coriell, L. L., and Scott, T. F. McN.: *Proc. Soc. Exper. Biol. & Med.* **69**: 341, 1948.

tology and pediatrics, University of Pennsylvania. Human skin used in most of their experiments was obtained at circumcision of children. The prepuce was cleaned preoperatively with soap, water and alcohol, other antiseptics being avoided. Usually within two hours after the operation the prepuce was further cleaned by bathing in a buffered isotonic sodium chloride solution, containing 0.5 per cent gelatin, penicillin and streptomycin. Previous studies had shown the antibacterial effectiveness and innocuous character of this solution. The connective tissue was carefully dissected off, leaving the epidermis and attached corium as thin as possible. Squares of the desired size were then planted on the chorioallantoic membranes of 10 day old embryonated hen's eggs. Bacterial contamination was rare. The 232 successful takes showed active proliferation of the epidermis and the establishment of chick circulation in the corium.

At the end of seven days the grafts were removed aseptically and placed in a sterile Petri dish. All the attached chorioallantois and any additional connective tissue which had grown in the corium were now trimmed away. The grafts were then transferred to the chorioallantoic membranes of a second 10 day embryonated egg. By this technic serial transfer could be continued at seven day intervals, apparently indefinitely. Of 124 regrafts only 7 failed to take.

The Philadelphia investigators found that both the initial grafts and the regrafts are readily inoculated with herpes simplex or with vaccinia virus, with the formation of characteristic inclusion bodies. Successful inoculations with herpes zoster virus were also made, thus confirming Goodpasture's³ single successful cultivation of this virus outside of the human body.

Aside from its possible use in the growth of viruses that cannot be cultivated by other methods, the skin graft technic has numerous possible applications to the solution of basic immunologic problems. The still unsolved problem of the relation of humoral and fixed cellular factors in acquired immunity was thus tested by Goodpasture.⁴ He grafted skin taken from chickens immune to fowl pox virus onto the chorioallantoic membrane. Tests showed that such grafts are fully susceptible to fowl pox infection. From this Goodpasture concluded that acquired fowl pox immunity is due in the main, at least, to humoral antibodies. These were presumably diluted out of the skin graft by the chorioallantoic circulation. Other interpretations are of course possible.

The possibility of making similar egg grafts of human mucous membranes, human blood vessels or other key human tissues has not yet been reported.

EXTRANEURAL MULTIPLICATION OF POLIOMYELITIS VIRUS

In 1936 Sabin and Olitsky¹ of the Rockefeller Institute reported the successful cultivation of poliomyelitis virus in test tube suspensions of human embryonic nervous tissue. Control tests with suspensions of tissues from human embryonic lungs, kidney, liver or spleen gave negative results. These observations were in accord with the currently accepted theory, which assumed that poliomyelitis virus is strictly neurotropic, incapable of invading any human tissue, except those of the nervous system.

Evans,² Rustigian³ and others have recently challenged this theory, on analogy with various poliomyelitis-like viruses of mice, which are known to be able to multiply in nonnervous tissues. The early test tube experiments of Sabin and Olitsky have therefore been repeated by Enders⁴ and his associates of Harvard University, using the improved tissue culture technic recently perfected by Weller⁵ for the cultivation of mumps virus.

The cultures consisted of embryonic human tissue fragments suspended in 3 cc. of a mixture of balanced salt solution and ox serum ultrafiltrate. Tissues from human embryos of two and one-half to four and one-half months were used as well as from a premature infant of seven months. Fragments were taken from the arm, legs, intestines and brains.

The primary inoculum of these tissue cultures consisted of 0.1 cc. of a suspension of mouse brain infected with the Lansing strain of poliomyelitis virus. In each test tube the nutrient fluid was removed as completely as possible at four to seven day intervals and replaced with fresh nutrient fluid. Subcultures on fresh tissues were made at eight to twenty day intervals.

Cultures composed chiefly of early embryonic skin, muscle and connective tissue have thus far been maintained for sixty-seven days. During this time the primary inoculum has been diluted approximately 10^{17} times, with little or no decrease in mouse infectivity titer. From this there was a calculated 10^{15} -fold multiplication of the virus. Cultures of early embryonic intestinal tissues gave a calculated multiplication of about 10^{12} -fold, by the end of two subcultures and seven changes in the nutrient fluid. With embryonic human brain tissues, the multiplication was also 10^{12} -fold.

Full identification of the virus was made by mouse inoculation, rhesus inoculation and serum neutralization tests. Tissue fragments removed after thirty days of cultivation in control uninoculated tubes apparently

contained viable cells, as indicated by normal staining properties of both nuclei and cytoplasm. In contrast, the majority of the cells in the inoculated cultures showed losses of normal staining reactions. From this and other evidence Enders concludes that multiplication of the Lansing strain of poliomyelitis virus conceivably occurs in cells not of nervous origin. Adult extra-neural human tissues, however, have not been tested.

Current Comment

THE NATIONAL HEALTH SERVICE TRIBUNAL

Under the National Health Service Act in Great Britain provision is made for disciplinary machinery which may be applied to members of the various professions that take part in the National Health Services. Such disciplinary action is in charge of a tribunal which considers representations that the continued inclusion of the name of any doctor, dentist, optician or pharmacist would be prejudicial to the efficiency of the service and that the person concerned should be "struck off." Obviously the "striking off" of the name of any professional man in such a manner would be equivalent to forcing him out of the practice of his profession. The hearings are held by a group including a permanent chairman appointed by the Lord Chancellor, a permanent member appointed by the Association of Executive Councils and one other person representing the profession involved. Any appeal from a decision of the tribunal goes to the Minister of Health and not to the courts. The regulations controlling the activities of the tribunal have been published. Obviously the medical and related professions in Great Britain no longer have any power or authority to govern themselves and the power of professional death or survival ultimately rests in the hands of one man, the Minister of Health. Apparently all that the Minister has to do is to publish hearings in "such manner as he sees fit." But even that decision is modified by the following: "The Minister or Tribunal may dispense with any requirements of these regulations respecting notices, applications, documents or otherwise in any case where it appears to the Minister or the Tribunal just and proper to do so."

HOMELESS MEN

A statistical report from the Welfare Council of New York City¹ indicates that the number of homeless men needing care in New York City has shown a rapid postwar rise. The committee obtained data from all public and private civic and social organizations which maintain or are concerned with lodging houses for homeless men in New York City. Composition of the so-called homeless men's group differed considerably from the expected. A three month study of men applying to one municipal lodging house demonstrated that 80 per cent were native-born Americans, 75 per

cent were white, 35 per cent had veteran status, and only one third had been in the city for less than one year. The majority were under 45 years of age, and an overwhelming majority were considered employable. Previous records of homeless men in the depression years 1932-1940 show a peak load during 1935, at which time the number of lodgings provided ran from 15,000 to 19,000 a day. The number gradually declined to 550 per day, in July and August of 1940. If the present upward trend continues the daily average may reach 3,000 to 3,500 per day. The problem presented was not attributed to advanced age, transiency, veteran or nonveteran status or alcoholism. Race, color and religious belief were not considered significant parts of the problem. A lack of opportunity as exemplified by the level of education obtained and lack of attachment to home or family are believed to be the two most significant factors. As present facilities for homeless men were considered inadequate, the committee recommended that a system be established for complete examination and registration by trained medical and social personnel. Individual specialized treatment would thus replace stereotyped handling methods now employed.

THE DISTINGUISHED SERVICE AWARD

The Distinguished Service Medal of the American Medical Association will be awarded for the twelfth time at the Inaugural Meeting Tuesday evening, June 7, 1949, during the Atlantic City Session. This Medal was first presented in 1938 to Dr. Rudolph Matas of New Orleans and has come to be recognized as one of the highest honors within the gift of the American Medical Association. In the years since the first award, the medal has been presented to Dr. James B. Herrick, Chicago; Dr. Chevalier Jackson, Philadelphia; Dr. James Ewing, New York; Dr. Ludvig Hektoen, Chicago; Dr. Elliott P. Joslin, Boston; Dr. George Dock, Pasadena, Calif.; Dr. George R. Minot, Boston; Dr. Anton J. Carlson, Chicago; Dr. Henry A. Christian, Boston, and Dr. Isaac A. Abt, Chicago. Any Fellow of the American Medical Association may submit nominations, which should be sent, together with a record of the scientific attainments of the nominees, to Dr. George F. Lull, Secretary of the Association, 535 North Dearborn Street, Chicago, who will refer them to the Committee on Distinguished Service Award. After careful consideration of all nominations received, the Committee will submit five names to the Board of Trustees, and the Board will select three of the five for presentation to the House of Delegates at its first meeting in Atlantic City. The House of Delegates makes the final selection by official ballot. Those to whom the Medal has been awarded thus far have all been men of the highest distinction, professionally and otherwise, and in their selection honor has accrued not only to the men themselves but also to the American Medical Association. Nominations should be sent to the Secretary of the Association immediately in order that they may be in hand at Atlantic City on Sunday, June 5.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

May 16, 1949.

Congress Accelerates Handling of Health Legislation

Confronted with the largest and most diversified volume of medical and public health bills in the memory of Capitol Hill officials, Congress has begun to speed up the pace of considering them in order to assure enactment of some of the measures—particularly those in the noncontroversial class—before the session ends. On May 12 two Senate subcommittees concluded public hearings on bills providing for increased federal funds for hospital construction, assistance to local public health departments and for medical research in specialized fields. By the end of May, hearings are expected to be well under way, conducted concurrently by House and Senate committees, on the more controversial national health bills.

May 23 is the newly designated date for opening of hearings by the Senate health subcommittee on the Taft-Smith-Donnell, Hill, Lodge and Thomas-Murray-Dingell bills. Originally scheduled to open a week earlier, a postponement was ordered when numerous prospective witnesses requested an extension of time. A group of Republican Senators and Representatives are reportedly working on still a different type of national health bill, which may be introduced and referred to the Murray subcommittee prior to the launching of its hearings. Meanwhile, hearings on the House side will be conducted by a subcommittee of which Representative J. Percy Priest (Democrat, Tennessee) is chairman.

Senators Hear Arguments for Increased Hospital Aid

Three days of public hearings on amendment of the Hill-Burton Hospital Survey and Construction Act were concluded May 9 by a special subcommittee of Senate Labor and Public Welfare Committee. All witnesses indorsed the amending bill, S. 614, some of them recommending certain minor changes.

Dr. George F. Lull said the A.M.A.'s official position on the proposed legislation, which would double federal support of hospital construction to \$150,000,000 annually, will be taken at the Atlantic City meeting in June.

George Bugbee, executive director of American Hospital Association, favored a flat 40 per cent as the federal share, rather than a flexible scale based on the various states' incomes. The sliding scale formula was indorsed by Lloyd C. Halverson, secretary of the National Grange Interim Committee on Health.

Other witnesses supporting passage of S. 614 were Dr. W. T. Sanger, president of Medical College of Virginia; E. A. van Steenwyck, Associated Hospital Service of Philadelphia; Dr. John A. Ferrell, North Carolina Medical Care Commission; Dr. D. V. Galloway, Mississippi Commission on Hospital Care; Dr. R. H. Hutcheson, Tennessee Health Commissioner; Dr. Albert D. Kaiser, Rochester (N. Y.) Health Officer; Rt. Rev. Msgr. George L. Smith, Catholic Hospital Association; Rev. John G. Martin, American Protestant Hospital Association; Dr. Hugh R. Leavell, Harvard School of Public Health, and several members of Congress.

\$125,000,000 Subsidy of Medical Care Plans Sought

Senator Hubert Humphrey (Democrat, Minnesota) on May 6 introduced a bill, S. 1805, authorizing federal subsidies of \$125,000,000 over a five-year period for cooperatives and non-profit associations operating prepaid medical care plans. The

bill's provisions are similar to those contained in the Truman Administration's compulsory health insurance bill (S. 1679). The government funds would be made available as loans and grants for acquisition, construction and equipping of physical facilities.

"Three national rural health conferences," said Sen. Humphrey, "under the auspices of the American Medical Association, have studied this problem and it is the consensus of the large farm organizations in the country that many of the problems of health they face can largely be worked out by the people themselves on a local community level. The granting of Federal assistance would give great impetus to the widespread demand for providing modern facilities to induce physicians to locate in rural areas."

He estimated that the \$25,000,000 annual assistance for five years would be sufficient to finance some 250 plans a year. In order to qualify, each plan would have to give assurance that there is no lay interference with practice of medicine; that its governing body is not dominated numerically by participating physicians, and that participation by patient-members and physicians is voluntary.

Broad Attack on Neurologic and Rheumatic Diseases Demanded

Five days of hearings, which began May 3 and ended May 10, on separate bills for acceleration of research in epilepsy, cerebral palsy, leprosy, arthritis and rheumatic conditions, and multiple sclerosis, elicited testimony by physicians and laymen, the latter including several patients. Supporting the arthritis bill were Drs. Russell L. Cecil, of Cornell; W. Paul Holbrook, of Tucson, Ariz.; Robert M. Stecher, of Cleveland, and several businessmen. The case for a stimulated, federally supported drive on multiple sclerosis was presented by Mrs. Lou Gehrig, Senator Charles W. Tobey and Drs. Herman Kabat, Tracy Putnam, Huston Merritt and C. H. Traeger. Spokesmen on cerebral palsy included Drs. Ross T. McIntire and Rene Caillet. Witnesses in behalf of an expanded program of leprosy control and education included Perry Burgess, president, Leonard Wood Memorial; Paul Strachan, American Federation of the Physically Handicapped, and Drs. Otis L. Anderson, Hartman Lichtwardt and F. C. Landrum. Another witness was Nick Farrell (an assumed name), who for five years was a patient at the U. S. Marine Hospital at Carville, La.

The Murray subcommittee, which conducted the hearings on these special character bills, terminated its two weeks of morning sessions on May 12 with taking of testimony on S. 904. This bill, sponsored by Senator Paul Douglas (Democrat, Illinois), provides for the institution of a federal child research program in matters of health and welfare. Testifying in support were Dr. Martha Eliot, Children's Bureau; Robert R. Sears, University of Iowa, and others.

Local Public Health Unit Bill Unanimously Supported

Passage of S. 522 or comparable legislation which would strengthen county and city public health agencies with federal funds was strongly urged at the Senate subcommittee hearings May 10-11 by physicians, medical educators, members of Congress and others. Among the witnesses were Surgeon General Leonard A. Scheele; Dr. James S. Simmons, dean of Harvard School of Public Health; Dr. James R. Miller, trustee of the American Medical Association, of Hartford, Conn.; Dr. Edwin L. Crosby, director, Johns Hopkins Hospital; Mrs. Dwight S. Perrin, a director of American Social

Hygiene Association; Dr. James E. Perkins, managing director, National Tuberculosis Association; Mrs. Stanley G. Cook, legislative chairman, National Congress of Parents and Teachers; Dr. Franklin M. Foote, executive secretary, National Society for Prevention of Blindness; Dr. Vlado A. Getting, Massachusetts Health Commissioner; Dr. Gaylord M. Anderson, secretary, Association of Schools of Public Health, and Dr. Haven Emerson, National Health Council.

Senate Passes School Health Services Bill

Without a dissenting vote, the Senate on April 29 passed S. 1411, a school health services bill authorizing \$35,000,000 annually in federal grants to the states for prosecution of programs designed to elevate standards of child health. This measure is not to be confused with S. 904, on which the Murray subcommittee was scheduled to hold public hearings May 11-12. The latter authorizes a broad research program in the field of juvenile welfare, including health; S. 1411 is strictly a child health bill, encompassing preventive, diagnostic and therapeutic care in such states as may choose to participate. Its enactment by the House and approval by the President are held probable.

Lobbying Reports Filed for First Quarter

National organizations which support or oppose prospective legislation have filed their financial reports for the first quarter of 1949, as required by the National Lobbying Act. The National Physicians Committee reported \$230,493 in contributions and \$130,969 in expenditures. The Committee for the Nation's Health certified to receipts of \$40,084 and expenses aggregating \$23,865. The American Medical Association reported that \$1,151,633 had been received into its educational fund up to April 7. During the quarter, Whitaker and Baxter received \$115,248 from the fund for furtherance of the educational campaign, \$76,654 of the total being for expenses. The American Hospital Association reported expenditures of \$13,418; the American Dental Association, \$4,916, and the American Optometric Association, \$2,097.

X-Ray Protection Manual Published

National Bureau of Standards has published a 42 page handbook, "Medical X-Ray Protection up to Two Million Volts," which is purchasable (15 cents) from the Superintendent of Documents, Washington 25, D. C. Bearing six illustrations and nine tables, the booklet is concerned with standards of safety in installation and operation of high voltage equipment utilized in diagnosis and treatment. It was prepared by a subcommittee of the National Committee on Radiation Protection. Recommended rules are included for working conditions, survey and inspection of installations, planning an x-ray installation and structural details of protective barriers.

Tydings Files Military Medical Bills

On April 25 Senator Millard Tydings (Democrat, Maryland), chairman of the Senate Armed Services Committee, filed separate bills to authorize commissioning of women physicians in the Regular Army Medical Corps and to liberalize the promotion system of the Army Medical Service Corps. The former (S.1687) provides for appointment of women in the Dental and Veterinary Corps, as well as Medical Corps, on the same basis as men. It also authorizes commissioning of women as pharmacists, sanitary engineers, optometrists and allied scientists in the Medical Service Corps. S.1688 defines precedence of Medical Service Corps personnel on the promotion list.

Child Research Bill to be Considered

May 11 and 12 have been scheduled for public hearings on the Douglas bill (S.904), which provides for a federal research program into medical, psychologic, sociologic and other aspects of child health. The American Parents Committee is a supporter of the bill and was instrumental in having it introduced by Senator Paul Douglas (Democrat, Illinois). The hearings will be conducted by the health subcommittee of the Senate Labor and Public Welfare Committee.

STATE LEGISLATION

Alabama

Bill Introduced.—S. 102 proposes to authorize any inhabitant of the state over the age of 21 years and of sound mind to arrange or prescribe, by an instrument in writing executed as a deed and filed for record in the office of the judge of probate of the county of his residence, for the disposition to be made, after death, of his body or any organ, member, or part thereof, provided the disposition of said body or part thereof is made for the purpose of advancement of medical science, or for the replacement of diseased or worn out parts of other human beings, or for the rehabilitation of human parts or other organs.

Colorado

Bill Enacted.—S. 84 was approved April 29, 1949. It creates a Colorado Commission on Alcoholism to study the problem of alcoholism, including methods and facilities available for the care, custody, detention, treatment, employment and rehabilitation of persons addicted to the intemperate use of spiritous or intoxicating liquors.

Florida

Bills Introduced.—H. 138 proposes to grant to expert witnesses a witness fee in such reasonable amount as the trial judge may determine, the same to be taxed as costs in the case. S. 459 and H. 706, to amend the medical practice act, propose that every person licensed under the laws of the State of Florida to practice medicine, surgery, osteopathic medicine, chiropractic, naturopathy, chiropody or any other kind or branch of the medical or material healing art, whenever actively engaged in the practice of same, or whenever holding himself out as a practitioner of same, shall cause to be placed and kept in a conspicuous place at each entrance to his office or usual place of business, words or proper abbreviations in block letters, in intelligible lettering not less than 2½ inches in height and 1 inch in width clearly denoting the particular kind or branch of the medical or material healing art he is licensed to practice. This same requirement is made of every sign wherever situated which the doctor may use.

Illinois

Bill Introduced.—S. 500 proposes the creation of a commission on the care of chronically ill persons to make a thorough investigation and study of the hospitalization and other care and treatment facilities available in the state for persons who are chronically ill, the adequacy of such facilities, the need of developing additional facilities for such purpose, the desirability of enacting enabling or corrective legislation to increase or improve such facilities, and all matters germane thereto. The investigation and study should embrace both governmental and private facilities.

Iowa

Bill Enacted.—S. 339 was approved May 5, 1949. It is a food and drug act and provides, among other things, that any drug sold at retail and containing any quantity of aminopyrine, barbituric acid, pituitary, thyroid or their derivatives must be labeled in accordance with the provisions of the act unless it is sold on the written prescription of a doctor, dentist or veterinarian.

Maryland

Bills Enacted.—S. J. Res. 15 has become Joint Resolution No. 11 of the Laws of 1949. It requires the governor to appoint a commission to study the laws of Maryland requiring licenses to engage in a trade or occupation. S. 216 has become chapter 442 of the Laws of 1949. It provides that no deputy state health officer shall practice medicine or engage in any other occupation which would conflict with the performance of his individual duties. S. 350 has become chapter 464 of the Laws of 1949. It amends the workmen's compensation act by providing for the appointment of a medical board consisting of three members, to be appointed by the governor from a list of nominees to be submitted by the deans of the medical departments of the University of Maryland and of the Johns Hopkins University and by the council of the Medical and Chirurgical Faculty of Maryland, each of these three agencies to submit a list of at least three persons, two of whom shall be especially experienced in occupational diseases, and one of whom shall be an experienced roentgenologist.

Massachusetts

Bills Introduced.—H. 2100, App. 1, proposes that the commissioner of public health shall be a graduate of an approved medical school and an accredited school of public health with three years' experience in a full time position in public health administration or, in lieu of graduation from a school of public health, he shall have had at least five years' experience in a full time approved position in public health. H. 2100, App. 18, proposes to require any physician having charge of the birth of a prematurely born infant to immediately notify the board of health and the board of public welfare of the town where the infant is born.

Michigan

Bills Introduced.—H. 483 proposes the creation of a board of chiropractic examiners and provides that licentiates under such a proposal would be authorized to practice a system of healing in the state of Michigan as taught by the approved colleges or schools of chiropractic and to use all necessary mechanical, hygienic and sanitary measures incident to the care of the body, but it shall not authorize the use of

compounded drugs, dentistry or optometry. Licentlates would be required to renew their license annually and, at the time of such renewal, to furnish satisfactory evidence that they have attended not less than a three-day postgraduate conference as authorized by the Michigan state board of chiropractic examiners and conducted by the Michigan state chiropractic society, incorporated, or its equivalent. S. 323 proposes to repeal the basic science law.

New York

Bills Enacted.—S. 412 has become chapter 733 of the Laws of 1949. It provides for the creation of a state commission to be known as the mental health commission to initiate, formulate and execute a master plan for the promotion of mental health programs within the state. S. 2666 has become chapter 819 of the Laws of 1949. It provides for the establishment of state scholarships for professional education in medicine and dentistry.

North Carolina

Bill Enacted.—H. 835 was approved April 23, 1949. It provides for the establishment of a commission to study problems relating to the care of the aged and the intellectually handicapped.

Ohio

Bill Introduced.—S. 338 proposes the creation of a state board of chiropractic examiners and defines chiropractic as the art and science of locating, the procedure preparatory to adjusting, and the adjusting by hand of the subluxations of the articulations of spinal column, which is deemed to be the twenty-four movable vertebrae, including the sacrum and coccyx and adjacent tissues, for the purpose of removing any interference with nerve transmission; but it shall not include surgery nor the administration or prescription of any drug included in materia medica, and it shall not be deemed to be a branch of the practice of medicine or surgery.

Oklahoma

Bill Introduced.—S. 261 proposes that all persons who practice the healing art or any branch thereof shall report to the State Department of Health the name and address of any person under their care who is afflicted with epilepsy, mental disease or any other disease which brings on momentary lapse of consciousness.

Pennsylvania

Bills Introduced.—H. Res. 68 proposes the appointment of a commission to study existing and proposed legislation pertaining to the regulation and licensure of the practice of diagnosis and treatment of human ills and its related limited branches with a view to combining all of the existing boards under one board which shall have representatives from each of the various branches and to make provision thereon for future additions. This commission would be required to report its findings and conclusions to the next regular session of the General Assembly. H. 313 proposes the creation of a state board of chiropractic examiners and defines chiropractic as a philosophy, science and art of things natural with the human body, a system of locating misaligned or displaced vertebrae of the human spine, the procedure preparatory to and the adjustment by hand of such misaligned or displaced vertebrae and other articulations and tissues of the human body together with the use of scientific instruments of analysis. S. 925 proposes an appropriation to the alcoholic information center and clinic for the purpose of expanding their facilities for research and training of personnel in the care, treatment and rehabilitation of alcoholic addicts. S. 952 proposes the creation of a state board of psychological examiners, one member of which shall be a qualified neuropsychiatrist who is a doctor of medicine licensed to practice medicine and surgery in Pennsylvania and experienced in mental and nervous diseases.

Bills Enacted.—H. 220 has become Act No. 123 of the Acts of 1949. It authorizes the department of health to investigate the subject of alcoholism in respect to rehabilitation and to compile and maintain reliable statistics indicating the effectiveness of any rehabilitation programs carried forward by state aided clinics for alcoholics, state hospitals and state-aided hospitals receiving alcoholics. H. 450 has become Act No. 123 of the Acts of 1949 and H. 451 has become Act No. 124 of the Acts of 1949. These laws provide that medical service plan corporations shall include the services of doctors of osteopathy. S. 444 was approved April 14, 1949. It provides that, to promote prevention, recognition and treatment of mental diseases, mental defect, epilepsy and inebriety, the Department of Welfare is empowered to establish, extend, operate, maintain and provide out-patient services in conjunction with mental institutions owned or operated by the commonwealth and separate psychiatric clinical services.

Tennessee

Bill Enacted.—H. J. Res. 24 was approved April 15, 1949. It provides for the appointment of a commission to make a thorough study of the needs for qualified physicians in various areas of the state and the facilities of the University of Tennessee Medical College to the end that the facilities of said Medical College may be enlarged and adequately adjusted to train sufficient physicians each year to keep pace with the increasing population and the medical needs thereof, considering the number of physicians who retire from active service and to provide an increasing degree of opportunity for a greater number of students to secure training in the medical profession.

Texas

Bills Enacted.—H. 103 was approved April 28, 1949. It is a basic science law requiring any person desiring to take an examination for a license to practice any branch of the healing art to first pass an examination in the basic sciences of anatomy, physiology, chemistry, bacteriology, pathology, and hygiene and public health. It exempts from its provisions any chiropractor who is a graduate of a school which was regularly organized and conducted as a chiropractic school in the United States at

the time of such graduation and who has practiced chiropractic one year immediately preceding the effective date of this act and who resided in Texas for two years immediately preceding the effective date of this act and who has never had a license to practice any branch of the healing art cancelled by any American or Canadian state, province or territory. H. 721 was approved April 27, 1949. It provides for the creation of a Texas board of chiropractic examiners and provides that any person shall be regarded as practicing chiropractic who shall employ objective or subjective means without the use of drugs, surgery, x-ray therapy or radium therapy, for the purpose of ascertaining the alignment of the vertebrae of the human spine, and the practice of adjusting the vertebrae to correct any subluxation or misalignment thereof.

Wisconsin

Bill Introduced.—A. J. Res. 63 proposes that the university board of regents be requested to advise the legislature of the reasons for the lack of growth in the medical school, and the number of applicants yearly denied admission to the medical school and the reasons therefor.

Coming Medical Meetings

American Medical Association, Atlantic City, June 6-10. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Neurology, French Lick, Indiana, French Lick Springs Hotel, June 1-3. Dr. Joe R. Brown, 19 Millard Hall, University of Minnesota, Minneapolis 14, Secretary.

American Academy of Tuberculosis Physicians, Atlantic City, Hotel Dennis, June 4. Dr. Oscar S. Levin, P. O. Box 7011, Denver 6, Colo., Secretary.

American Association of Railway Surgeons, Chicago, Drake Hotel, June 30-July 2. Dr. Chester C. Guy, 5800 Stony Island Ave., Chicago 37, Secretary.

American Association of the History of Medicine, Lexington, Ky., Lafayette Hotel, May 23-24. Dr. Benjamin Spector, 416 Huntington Ave., Boston 15, Secretary.

American College of Chest Physicians, Atlantic City, Ambassador Hotel, June 2-5. Mr. Murray Kornfield, 500 N. Dearborn St., Chicago 10, Executive Secretary.

American College of Radiology, Atlantic City, Chalfonte-Haddon Hall, June 5. Mr. William C. Stronach, 20 N. Wacker Drive, Chicago 6, Secretary.

American Dermatological Association, Hot Springs, Va., May 25-28. Dr. Louis A. Brunsting, 102 Second Ave. S.W., Rochester, Minn., Secretary.

American Gastro-Enterological Association, Atlantic City, Claridge Hotel, June 3-4. Dr. Dwight L. Wilbur, 655 Sutter Street, San Francisco 2, Secretary.

American Gastroscopic Society, Atlantic City, Claridge Hotel, June 3-4. Dr. J. Edward Berk, 255 S. 17th St., Philadelphia 3, Secretary.

American Goiter Association, Madison, Wis., Hotel Loraine, May 26-28. Dr. Thomas C. Davison, 478 Peachtree St., N.E., Atlanta 3, Ga., Secretary.

American Medical Women's Association, Atlantic City, June 4-5. Dr. Augusta Webster, 104 S. Michigan Ave., Chicago, Secretary.

American Neurological Association, Atlantic City, Chalfonte-Haddon Hall, June 13-15. Dr. H. Houston Merritt, 710 W. 168th St., New York 32, Secretary.

American Ophthalmological Society, Hot Springs, Va., The Homestead, June 2-4. Dr. Maynard C. Wheeler, 30 W. 59th St., New York, Secretary.

American Proctologic Society, Columbus, Ohio, May 31-June 4. Dr. W. Wendell Green, 1838 Parkwood Ave., Toledo 2, Ohio, Secretary.

American Psychiatric Association, Montreal, Canada, May 23-27. Dr. Leo H. Bartemeier, General Motors Bldg., Detroit 2, Secretary.

American Radium Society, Atlantic City, June 5. Dr. Hugh F. Hare, 605 Commonwealth Ave., Boston 15, Secretary.

American Therapeutic Society, Atlantic City, June 2-5. Dr. Oscar B. Hunter, 915 Nineteenth St. N.W., Washington, D. C., Secretary.

Association for the Study of Internal Secretions, Atlantic City, June 3-4. Dr. Henry H. Turner, 1200 N. Walker St., Oklahoma City 3, Secretary.

Idaho State Medical Association, Sun Valley, June 20-23. Dr. Alfred M. Popma, 220 N. First St., Boise, Secretary.

International Congress on Rheumatic Diseases, New York, Hotel Waldorf-Astoria, May 30-June 3. Dr. Philip S. Hench, Mayo Clinic, Rochester, Minn., Chairman, American Committee.

Maine Medical Association, Poland Spring, Poland Spring House, June 19-21. Dr. Frederick R. Carter, 142 High St., Portland 3, Secretary.

Massachusetts Medical Society, Worcester, May 24-27. Dr. H. Quimby Gallupe, 8 Fenway, Boston 15, Secretary.

New Hampshire Medical Society, Newcastle, Hotel Wentworth, June 14-15. Dr. Carleton R. Metcalf, 5 S. State St., Concord, Secretary.

Society for Investigative Dermatology, Atlantic City, Ritz Carlton Hotel, June 11-12. Dr. S. William Becker, 55 E. Washington St., Chicago 2, Secretary.

Society of Biological Psychiatry, Atlantic City, Chalfonte-Haddon Hall, June 12. Dr. George N. Thompson, 1136 W. Sixth St., Los Angeles, Secretary.

South Dakota State Medical Association, Yankton, May 22-24. Dr. Roland G. Mayer, 224 S. Main St., Aberdeen, Secretary.

Southeastern Surgical Congress, Biloxi, Miss., May 23-26. Dr. Benjamin T. Beasley, 45 Edgewood Ave. S.E., Atlanta 3, Ga., Secretary.

Western Branch of American Public Health Association, Los Angeles, Hotel Biltmore, May 30-June 1. Mr. Walter S. Mangold, University of California, Berkeley, Calif., Secretary.

GOVERNMENT SERVICES

SECRETARY OF DEFENSE

RESIDENCIES AVAILABLE

The University of Minnesota Medical School and its affiliated hospitals report that a number of residency vacancies have occurred as the result of the postponement of appointment dates of applicants who were tentatively selected for residencies to begin July 1, but whose appointments are being postponed so

that the men may be available to help meet the urgent need of the armed forces for medical officers. The vacancies are distributed over most of the medical and the surgical specialties. Substitutes for these appointments will be selected from the applicants who have had active military service as medical officers.

ARMY

MEETING OF MEDICAL CONSULTANTS

The Advisory Council, Society of U. S. Medical Consultants in World War II, met April 16 in the Pentagon, Washington, D. C. Dr. Henry M. Thomas Jr., of Johns Hopkins Hospital, Baltimore, opened the meeting. Col. Paul I. Robinson, Chief, Personnel Division, Surgeon General's Office, discussed the officer procurement program. Col. A. H. Schwichtenberg, Chief, Medical Plans and Operations, Surgeon General's Office, discussed recent policy decisions on basic operational problems. The various committees presented progress reports. Reporting for the consultants in the Zone of Interior Committee were Dr. Garfield G. Duncan, Philadelphia, and Lieut. Col. W. F. Bowers, Chief, Surgical Consultants Division, Office of the Surgeon General; for the Reserve Affairs Committee, Dr. Frank B. Berry, New York, and Col. Charles K. Holmes, Chief, Civilian Components Branch, Personnel Division, Surgeon General's Office, and for the Residency Training Program, Dr. Yale Kneeland, New York, and Lieut. Col. Fred J. Fielding, Chief, Career Guidance Section, Personnel Division, Surgeon General's Office. The meeting was then open to a general discussion.

CONSULTANT TEAM GOES TO GERMANY

Five medical consultants left April 18 for Germany to devote about thirty days to visiting hospitals where they will conduct teaching clinics and be available for consultation and care of patients. The team comprises Drs. Frank A. Stewart, Tulsa, Okla. (orthopedics); Shirley H. Baron, San Francisco (ear, nose and throat); Staige D. Blackford, Charlottesville, Va. (internal medicine); Elwin M. Williamson, Kalamazoo, Mich. (neuropsychiatry), and Col. Warner F. Bowers, Chief, Surgical Consultants Branch, Surgeon General's Office.

PROPOSED COURSE FOR RESERVE NUTRITION OFFICERS

Reserve and former nutrition officers met April 20 in Detroit in conjunction with the meeting of the Federation of American Societies for Experimental Biology. Plans are being formed for a two week refresher course for reserve nutrition officers to be held at the Medical Nutrition Laboratory in Chicago as part of the active duty training program. Establishment of the course will depend on the number of reserve officers willing to attend. Those interested should notify the Chief, Nutrition Branch, Medical Service Corps, Surgeon General's Office, Department of the Army, Washington, D. C., at once.

UNESCO BOOK COUPONS

The Army Medical Library has agreed to accept UNESCO book coupons in payment for its photoduplication services in "soft currency" countries. These coupons, which are redeemable by UNESCO, are currently offered for sale by UNESCO throughout the world. Doctors wishing microfilm may buy the coupons with their local currency. It is expected that this device will expand even further the Library's widespread photoduplication activities.

ADDITIONAL ADVANCED TRAINING OF MEDICAL OFFICERS

The following Medical Department officers have been accepted for advanced training by civilian schools and hospitals:

Name	Institution	Course
James A. V. Galvin, Major	University of Illinois, Chicago	Psychiatry
George M. Sabin, Jr., Major	Manhattan General Hospital, New York	Laryngoscopy and intubation
Marshall B. Atkinson, Major	Manhattan General Hospital, New York	Laryngoscopy and intubation
Albert K. Schoenbucher, First Lieutenant	Maryland General Hospital, Baltimore, Maryland	Obstetrics and gynecology
William Stone, Captain	University of Utah, Salt Lake City, Utah	Anesthesiology
Charles I. Bryans Jr., Captain	University Hospital, Augusta, Georgia	Obstetrics and gynecology
Grady W. Phillips, Captain	Chicago Lying-in Hospital, Chicago	Obstetrics and gynecology
Richard L. Kasper, First Lieutenant	Los Angeles County Hospital	Ophthalmology
Arnold J. Brody, First Lieutenant	Yale Medical School, New Haven, Conn.	Medicine
James L. McNeil, First Lieutenant		Pediatrics
Edwin J. Westfall, First Lieutenant	Graec Hospital, Detroit	Internal medicine
George C. Weinland, First Lieutenant	Indiana University, Indianapolis	Neuropsychiatry
Frank J. Cozzetto, First Lieutenant	Colorado General Hospital, Denver	Internal medicine

BEQUEST TO ARMY MEDICAL LIBRARY

The will of Mrs. Emma Wheat Gillmore, under which the Army Medical Library is a beneficiary, has been admitted to probate in New York City. After paying expenses incident to settlement of the estate, it is estimated that this bequest will amount to about \$23,000. Mrs. Emma Wheat Gillmore, herself a Doctor of Medicine, was the widow of Capt. Robert Tracy Gillmore, medical reserve corps, who died while serving at Fort Oglethorpe, Ga., in World War I.

PERSONALS

Major Jack P. Love, who has been appointed a White House aide, is the first M.S.C. officer to be so appointed. The Army, the Air Force and the Navy each has seven officers for detail as aides at the White House. Their duties are to assist in formal ceremonies and social functions. Major Love received a B.S. in Hospital Administration from Northwestern University in 1948, graduated from the officers' candidate school at Carlisle Barracks, Pa., in 1941, and served about four years during the War in the Southwest Pacific Theater.

Major Maxwell Dauer, M.S.C., who was recently certified in x-ray and radium physics by the American Board of Radiology, is the first Army Medical Department officer to be certified in this field. He is assigned to the Atomic Energy Commission. Major Dauer formerly was an instructor in roentgenology at the Army Medical School. He was radiologic monitor for the Bikini atom bomb tests and a member of the Atomic Energy Commission proving ground group for the Eniwetok atom bomb tests.

AIR FORCE

NEW REHABILITATION PROGRAM

A new rehabilitation program, designed to effect more rapid convalescence of hospitalized airmen, will be initiated by the U. S. Air Force base hospitals on July 1. The Air Force program, according to Major General Malcolm C. Grow, the Air Surgeon, will go a step further and provide part time work fitted to the stage of convalescence of the patient and his regular duty assignment. The program will require close cooperation between base surgeons and unit commanders. The surgeons will be responsible for determining when a patient is capable of working on a part time basis and for selecting the type of work to be assigned. Unit commanders will plan suitable schedules of work. During the convalescent period, the airmen will remain in the custody of the hospital with the exception of the work period. Rehabilitation needs will be determined by the surgeons on the basis of the nature of the

injury or illness of the airmen involved. Each airman will receive a daily check-up to determine the type of work which will best fit his needs.

CERTIFICATES FOR FORMER FLIGHT SURGEONS

Certificates are now ready for mailing to former medical officers who served during the war with the designation of flight surgeons. The certificates, which are suitable for framing, indicate that the officers concerned were graduated from the aviation medical examiner's course given at the U. S. Air Force School of Aviation Medicine, Randolph Air Force Base, Texas. Those eligible to receive the certificates may secure them by writing to The Air Surgeon, Headquarters, U. S. Air Force, Washington 25, D. C. Officers now on active duty are not eligible to receive the certificates.

NAVY

NEW NAVAL HOSPITAL

The new Naval Hospital at Beaufort, S. C., costing \$9,500,000, was commissioned April 29, replacing the present inadequate facilities at the Marine Recruit Depot at Parris Island, which will be decommissioned. The new hospital was designed to be a 500 bed hospital but was reduced to 300 beds because of a limitation of funds.

Among those speaking at the ceremonies were Representative L. Mendel Rivers, South Carolina; Senator Olin D. Johnston, South Carolina; Representative Harry R. Sheppard, California; Governor J. Strom Thurmond of South Carolina; Major General Alfred H. Noble, Commanding General, U. S. Marine Recruit Depot, Parris Island, S. C.; Rear Admiral C. A. Swanson, Chief of the Bureau of Medicine and Surgery, and Rear Admiral John J. Manning (C.E.C.), Chief, Bureau of Yards and Docks. Other prominent guests present were Representative Robert L. F. Sikes, Florida; Rear Admirals A. H. Dearing, J. B. Logue, B. Groesbeck and C. V. Rault and Captain Nellie J. Dewitt, Superintendent of the Navy Nurse Corps.

COURSE IN SPECIAL WEAPONS AND RADIOACTIVE ISOTOPES

About 300 Naval reserve officers and 6 Royal Canadian medical reserve officers attended the five day course in Medical Aspects of Special Weapons and Radioactive Isotopes which began April 25 at the Naval Medical School, Bethesda, Md. In addition to Naval officers and representatives of other government agencies, the following civilians were among the speakers: Dr. Shields Warren, Dr. Charles F. Geschickter, J. B. Trunnell, Dr. Yale Kneeland Jr., Herbert Friedman, Philip H. Abelson, Karl Z. Morgan, Dr. Howard Andrews and R. E. Lapp.

THE EDWARD RHODES STITT LIBRARY

The Medical Library at the U. S. Naval Medical School, Bethesda, Md., has been designated by the Surgeon General as the Edward Rhodes Stitt Library in honor of the late Rear Admiral Stitt, the Surgeon General of the Navy from 1920 to 1928. Mrs. Stitt presented a collection of the late Admiral's civilian scientific medals, fraternal and honorary keys to the library, where they will be placed on permanent display.

COURSE ON FITTING ARTIFICIAL LIMBS

A ten day course of instruction on the manufacture and use of artificial limbs was recently completed by representatives of governmental and civilian artificial limb shops at the Naval Hospital, Mare Island, Calif. The course included fitting of artificial limbs employing the new functional ankle and soft

socket for below knee amputees and the functional hinges and suction sockets for arm amputees. These devices were originated and introduced by the Naval Hospital, Mare Island.

The course was conducted by the staff of the artificial limb department of that hospital, under the direction of Capt. W. H. Perry, U.S.N., and Comdr. T. J. Canty, U.S.N., who heads the artificial limb department. Eleven amputees from the San Francisco Bay area were selected as working models. On completion of the course both the students and the patients were unanimous in their praise of the work and the finished limbs.

PERSONALS

Lieutenants (jg) Cyril J. Honsik of Oak Park, Ill., Gerald A. Martin of Maryland and William R. True of Bethany, Mo., have been appointed to the Regular Navy Medical Corps from an active reserve status.

Lieut. Comdr. Newell Nay, M.C.R., of Long Beach, Calif., has been nominated for recall to active duty and will report to the Naval Air Station, Quonset Point, R. I.

Lieut. Boyd K. Black and Lieut. (jg) Martin O. Greaney Jr. have been nominated for postgraduate instruction in neuropathology at Mayo Clinic and a residency in obstetrics and gynecology at the Columbia Hospital for Women, Washington, D. C., respectively.

Lieut. (jg) John R. Kimball, M.C.R., has been nominated for his first active duty as an intern at the Naval Hospital, San Diego, Calif.

Capt. Newton T. Saxl of New York City has been nominated for voluntary recall to active duty and will be stationed at the Naval Receiving Station, Brooklyn.

Comdr. Russell H. Blood, M.C.R., of Los Angeles, has been nominated for recall to active duty.

Lieut. Gustave T. Anderson of North Platte, Neb., has been appointed to the Regular Navy Medical Corps from an active reserve status.

Capt. Lyle A. Newton, M.C., and Comdr. John E. Gorman, M.C., have been certified by the American Board of Urology and the American Board of Internal Medicine, respectively.

Comdrs. Joseph M. Coppoletta, North Hackensack, N. J., and Walter C. Tilden, Weems, Va., have requested recall to active duty in the Medical Corps Reserve.

Lieut. (jg) John H. Schulte, who recently was appointed in the Regular Navy from the reserve corps, has been nominated for duty as a resident in internal medicine at the Naval Hospital, San Diego, Calif.

Lieut. Lester W. Fix, M.C., has been nominated for duty under instruction in anatomic pathology at the University of Illinois College of Medicine, Chicago.

PUBLIC HEALTH SERVICE

BCG VACCINATION FOR INDIAN CHILDREN

Plans have been completed for a program of BCG vaccination at several Indian reservations and units of the Indian Service. Cooperating in this program will be the Bureau of Indian Affairs and the Public Health Service with Dr. Arthur W. Dahlstrom, Tuberculosis Control Officer, Bureau of Indian Affairs, in charge.

The Bureau of Indian Affairs will be responsible for administration and promotion of the evaluation program and for the collection of all technical data during the tuberculin testing and BCG vaccination activities, and it will furnish the personnel and supplies required for these activities.

The Division of Tuberculosis will provide technical guidance in developing the evaluation study and will train professional personnel assigned to the project by the Bureau of Indian Affairs. The Division also will be responsible for the research aspects of the project and will analyze the results when the testing and vaccination activities have been completed.

Dr. Albert P. Knight of the Immunization Evaluation Section, Division of Tuberculosis, Public Health Service, will serve as Public Health Service consultant to the joint evaluation program. Dr. Knight also is in charge of the training program which began on March 21, in Albuquerque, N. M.

The mass tuberculin testing and vaccination activities under the study will continue until June of this year at reservations and units of the Indian Service located in Arizona, Colorado, Idaho, Montana, New Mexico, North Dakota, South Dakota, Utah and Wyoming. About 18,000 children attending Indian Service schools in these areas will be tuberculin tested, and non-reactors will be offered BCG vaccination.

ESTABLISH INSTITUTE OF MENTAL HEALTH

A National Institute of Mental Health, authorized by the Seventy-Ninth Congress, has been created in the National Institutes of Health. The new institute will continue to program formerly carried out by the Division of Mental Hygiene of the U. S. Public Health Service. This program is directed toward gaining more knowledge of the cause, prevention and control of mental illness and the training of personnel and developing of community mental health facilities. The director of the National Institute of Mental Health will be Dr. Robert H. Felix, who has been Chief of the Division of Mental Hygiene since 1944. Dr. Felix will serve under the general supervision of Dr. R. E. Dyer, Director of the National Institutes of Health. Dr. Felix is a specialist certified by the American Board of Psychiatry and Neurology. The Advisory Mental Health Council, consisting of six civilian authorities in this field, will assist in formulating policies for the new institute. Temporarily, headquarters of the National Institute of Mental Health will be located in the Federal Security Building, Washington, D. C. Transfer will be made to the National Institutes of Health in Bethesda as soon as new buildings now under construction are completed.

TESTS CONDUCTED AT DONORA

At the request of the city of Donora, the Pennsylvania State Health Department and the C.I.O. Steelworkers, the Public Health Service conducted tests to determine the cause of last fall's disaster at Donora. Contrary to reports that many persons had been affected by the tests, Surgeon General Leonard A. Scheele stated that no evidence had been found of any person's suffering serious effects from the four day tests, which ended on April 21.

INFLUENZA STUDY PROGRAM

An exhibit showing the work of the Influenza Study Program of the World Health Organization, particularly as it operates in the United States, has been prepared by the Office of Scientific Reports, National Institutes of Health. The exhibit shows the locations of participating laboratories in the United

States and electron micrographs of various strains of influenza virus. Several of the micrographs were furnished by the World Influenza Centre, London. They show strains isolated in Europe during 1949, and some include the filamentous forms of virus reported by the World Influenza Centre. The exhibit was scheduled for showing before the Society of American Bacteriologists in Cincinnati, May 17-20, and at the Third Annual Meeting of the Marine Hospital Medical and Dental Association at Stapleton, Staten Island, N. Y., May 12-14.

PERSONNEL ON LOAN TO GREECE

A number of Public Health Service officers and technicians are on loan to the Economic Cooperation Administration Mission to Greece. Medical Director O. F. Hedley of the Public Health Service is head of the Public Health Division of the mission, which works in close cooperation with the Greek Government, the Greek Red Cross and other rehabilitation and reconstruction agencies there. The mission, the World Health Organization and other health agencies in Greece have been cooperating on malaria control, tuberculosis control and environmental sanitation. Senior Surgeon Leslie W. Knott, assistant director of the Public Health Division, is returning to the United States and will be replaced by Senior Surgeon Robert L. Cherry. Senior Surgeon Fred W. Love, who is in charge of tuberculosis work of the division, will also return and will be replaced by Senior Assistant Surgeon Gerald R. Clark.

ALL STATES EXCEPT NEVADA HAVE COMPLETED HOSPITAL SURVEYS

The Public Health Service reports that as of April 8 all of the fifty-three states and territories, with the exception of Nevada, have completed surveys of their hospital facilities and passed legislation to enable them to participate in the federal hospital construction program. A total of 643 applications with an estimated total cost of \$366,000,000 had received initial approval by January 1. The federal contribution to these projects is estimated at \$107,000,000.

CANCER RESEARCH GRANTS

Following recommendation by the National Advisory Cancer Council, the Surgeon General has approved research grants totaling \$671,200 to finance research in cancer. Among the grants was \$18,306 to Yale Medical School to determine whether cell-destroying viruses may show the properties of cancer-inducing agents. Another grant for \$12,312 to Washington University School of Medicine, St. Louis, is for an investigation of weight loss in persons with advanced cancer.

PERSONALS

Lawrence B. Hall, sanitary engineer, Public Health Service, has left for Iran to help in that country's fight against malaria. Mr. Hall's services were requested by the Iranian Embassy in Washington under terms of the Smith-Mundt Act, an educational program in which the United States gives technical assistance on a reciprocal basis with other nations. The Iranian Government will pay Mr. Hall's foreign allowance, travel and living expenses.

Dr. Moises Polak of Buenos Aires has arrived at the National Cancer Institute, Bethesda, Md., for a three month special fellowship during which he will apply silver impregnation technics to the study of experimental cancer in animals. These technics have been used routinely in Dr. Polak's laboratory, but they have been little used in the United States.

On March 17 Dr. Robert H. Huebner of the National Institutes of Health, Bethesda, Md., was presented with the 1948 award of the Washington, D. C., Academy of Sciences "in recognition of his contributions to our knowledge of the transmission of certain rickettsial diseases," especially rickettsialpox and Q fever.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CONNECTICUT

Bicentenary of Edward Jenner.—An exhibition commemorating the two hundredth anniversary of the birth of Edward Jenner on May 17 is on display this month in the Medical Library of Yale University School of Medicine, New Haven. From Yale's Harvey Cushing Collection are shown copies of all the early editions of "An Inquiry into the Cause and Effects of the Variolae Vaccinae," which contained Jenner's most important conclusion: "that the cowpox protects the human constitution from the infection of smallpox." Subsequent writings are shown, including "Further Observances" and "Continuations," that Jenner published in answer to criticisms that arose concerning his discovery and to record further cases. Among them are several translations of his works in Latin, German, French, Dutch and Russian. Special attention is given to the part played by Thomas Thacher of Boston, whose "Brief Rule" was the earliest medical document printed in the colonies. It also illustrates the roles of Cotton Mather, Zabdiel Boylston and Benjamin Waterhouse, early advocates of inoculation. Also shown is Benjamin Franklin's famous communication on the subject, issued in 1759. An original pastel drawing of Jenner by John Raphael Smith, original Jenner letters, caricatures inspired by the vaccination controversy and other related materials are on exhibit.

DISTRICT OF COLUMBIA

Personal.—Dr. Warren Andrew, chairman, department of anatomy, George Washington University School of Medicine, Washington, D. C., who has been visiting professor of anatomy at Washington University School of Medicine in St. Louis, returned to the university March 15, and will be in charge of the histology class for the remainder of the course.

Noyes Foundation Aids Students.—The Jessie Smith Noyes Foundation has rendered financial assistance to fifteen Negro medical students during the current academic year. The awards ranged from a loan of \$300 to a grant of \$1,400. Nine students at Howard, one at Meharry and five at other institutions received the awards. The Noyes Foundation has assisted thirty-nine students in all categories since it was established in July 1947 by Mr. Charles F. Noyes, New York realtor, in memory of his wife.

ILLINOIS

Dr. Jerome J. Sievers Resigns.—Dr. Jerome J. Sievers, Springfield, chief of the Division of Communicable Diseases, has resigned from the Illinois State Department of Public Health, effective May 30, to enter private practice in California. Dr. Leonard M. Schuman, Springfield, chief of the Division of Venereal Diseases, will head the Division of the Communicable Diseases temporarily in addition to his regular duties. This resignation leaves vacancies in fourteen posts requiring doctors in the department of public health.

Chicago

Presbyterian Interne-Resident Reunion Dinner.—This dinner will be held in the Casino Room of the Congress Hotel, June 14, at 6:30 p. m. Reservations should be made through the medical director's office of the hospital. Clinics and tours through the hospital are being arranged for the day.

Ernest E. Irons Lecture.—Dr. Sidney Farber, Children's Medical Center, Boston, will give the 1949 Ernest E. Irons Lecture for Kappa chapter of Nu Sigma Nu, University of Chicago at 8 p. m., May 26 in Pathology 117, Albert Merritt Billings Hospital. His subject will be "Experimental Chemotherapy of Cancer with Particular Reference to Folic Acid Antagonists."

Graduate Courses.—The Cook County Graduate School of Medicine has arranged two courses for the summer months. A two weeks' intensive personal course in the Diagnosis and Treatment of Congenital Malformations of the Heart will be presented by Dr. Benjamin M. Gasul beginning June 13. Another two weeks' course in Cerebral Palsy will be presented by Dr. Meyer A. Perlstein beginning August 1.

Loyal Davis Named to Grunow Chair in Surgery.—Dr. Loyal Davis, professor of surgery and chairman of the department in the Northwestern University Medical School, and chief of staff of Passavant Memorial Hospital, has been appointed the first Grunow Professor of Surgery at the university. The chair in surgery was established last February with a gift from the Lois Grunow Memorial Clinic, Inc., of Phoenix, Ariz. (THE JOURNAL, February 19, p. 536). Dr. Davis has been a member of the faculty since 1925 and chairman of the department of surgery since 1932. The professorship was named in memory of Lois Grunow, who died at the age of 7. Her father, William C. Grunow, of Lake Geneva, Wis., chairman of the memorial clinic's board of directors, founded the clinic in 1930. His support of both the Phoenix institution and research in surgery at Northwestern is the result of his desire to improve surgical technics and to make good surgical care available to children.

KENTUCKY

The Gross Lecture.—The annual lecture in honor of Dr. Samuel D. Gross, former professor of anatomy and surgery at the University of Louisville School of Medicine, was given by Dr. Warren E. Cole, Chicago, April 28, on "Diseases of the Gall Bladder." Phi Chapter of Phi Delta Epsilon sponsored the lecture.

Dentists Oppose Political Medicine.—At the annual convention of the Kentucky State Dental Association in Louisville April 5 a resolution was adopted criticizing political medicine and dentistry and calling on Congressmen to vote against pending bills which would set up a socialistic system of medical and dental care.

Poliomyelitis Planning Conference.—A coordinated program to combat possible poliomyelitis epidemics in the state was discussed at the state's first Poliomyelitis Planning Conference in Louisville April 26. Hospital facilities, nursing care, medical aid and trained personnel available were studied. Refresher courses for doctors, nurses and nurses aids on treatment of poliomyelitis are already being conducted or plans proposed.

LOUISIANA

Alpha Omega Alpha.—The "Beta of Louisiana" chapter of Alpha Omega Alpha was installed at the Louisiana State University School of Medicine, New Orleans, on April 28. It is the fifty-second chapter in medical schools of the United States and Canada. Guests of honor included Dr. William W. Frye, associate dean of the Tulane University School of Medicine and dean-elect of Louisiana State University School of Medicine, who gave the installation address. The charter was conferred by Dr. Walter L. Bierring, national president of Alpha Omega Alpha, and accepted by Dr. Edgar Hull, acting dean of the medical school. Dr. Josiah J. Moore, national secretary of Alpha Omega, presented the certificates and keys to the initiates.

MARYLAND

Public Health Anniversary.—The Maryland State Department of Health on May 6 celebrated the seventy-fifth anniversary of its founding in the Baltimore office of Dr. Nathan R. Smith. Maryland was the sixth state to organize a board of health. The work began with the prevention and control of epidemics, improvement of sanitary conditions and reporting of deaths. In 1922 it entered the field of personal hygiene with the provision of educational and preventive services for expectant mothers. The dental program, school health work and concern for industrial health problems followed. Curative services were included in 1945 along with the medical care program.

MASSACHUSETTS

Dr. Berry Appointed Dean at Harvard.—Dr. George P. Berry, professor of bacteriology and associate dean of the University of Rochester (N. Y.) School of Medicine and Dentistry, has been appointed dean of the Harvard Medical School, Boston, effective July 1, to succeed Dr. C. Sidney Burwell, who has resigned to devote his full time to teaching and research. Dr. Berry will also hold an appointment as professor of bacteriology. A graduate of Johns Hopkins University School of Medicine, 1925, he has served in Johns Hopkins Hospital in Baltimore and in the Hospital of the Rockefeller Institute for Medical Research in New York, as well as in the Rockefeller Institute itself. He has held administrative posts in the University of Rochester School of Medicine and Dentistry since 1932, when he became assistant dean, and was promoted to associate dean in 1947. A lieutenant commander in the Medical Corps, U. S. Naval Reserve, since 1941, Dr. Berry

participated in the atomic bomb tests at Bikini atoll in 1946. He is associate editor of the *Journal of Immunology* and of *Bacteriological Reviews* and a member of the editorial board of the *Journal of Bacteriology*. He has conducted research on psittacosis, yellow fever and encephalitis and is especially interested in the mechanisms of virus infections. A specialist certified by the American Board of Internal Medicine, Dr. Berry is a former president of the American Association of Immunologists, has served as vice president of the association of American Medical Colleges and is a member of numerous scientific societies. He is a director of the Josiah Macy Jr. Foundation and a member of the Division of Medical Sciences, National Research Council.

State Medical Meeting.—The Massachusetts Medical Society will hold its annual meeting in the Memorial Auditorium in Worcester May 24-26 under the presidency of Dr. Daniel B. Reardon, Quincy. The scientific sessions will open with the Annual Oration by Dr. C. Sidney Burwell, dean of Harvard Medical School, on "Responsibilities of Medical Education." Out-of-state speakers include:

George Crile Jr., Cleveland, The Management of Thyroid Disease.
H. Houston Merritt, New York, Diagnosis and Management of Chronic Recurrent Headache.
William B. Snow, New York, Mechanical and Clinical Considerations in the Medical Care of Patients with Low Back Pain.
Granville A. Bennett, Chicago, Interpretation and Management of Chondromatous Tumors in Bone.
Robert D. Dripps, Philadelphia, Pitfalls in Anesthesiology.
F. Bayard Carter, Durham, N. C., Indications for Total Hysterectomy.
Penry L. B. Ebbett, Houlton, Me., Obstetrical Problems in Rural Districts.

The Shattuck Lecture will be delivered by Dr. Paul D. White, Boston, on "La Médecine du Cœur." At the dinner meeting Wednesday evening the guest speaker will be Roscoe Pound, LL.D., Boston, whose subject will be "The Professions in the Society of Today." The Woman's Auxiliary will meet in Worcester May 24-25.

NEW YORK

Dr. Kolb Retires.—Dr. Edwin P. Kolb, Holtsville, L. I., on April 30 retired after thirty-three years as superintendent of the Suffolk Sanatorium. Under his administration the hospital grew from a 44 bed institution to one with a potential capacity of over 200. Dr. Cecil L. Schultz, superintendent of the Estelle and Walter C. Odell Memorial Sanatorium, Newburgh, will succeed Dr. Kolb.

Grant to University of Buffalo.—A grant of \$2,150 for this year has been made to the University of Buffalo School of Medicine for special work in promoting "doctor-patient relationships." The grant was made by the Lamb Foundation, which was established by Dr. Robert B. Lamb, a retired psychiatrist of Harmon-on-Hudson. Most of the sum will be used for full support to a fellow in psychosomatic medicine at the Edward J. Meyer Memorial Hospital and partial support to a Meyer hospital resident in medicine who has had psychiatric training.

Spotted Fever Vaccine Distribution Discontinued.—The U. S. Public Health Service is discontinuing the preparation of Rocky Mountain spotted fever vaccine for the state health department, since the material is now available from commercial manufacturers. The state department will purchase vaccine for distribution in known endemic areas in the state, Long Island counties of Suffolk and Nassau. In 1948 only 20 cases and 1 death were reported, all from Suffolk County. Health officers or other physicians who wish to continue to use the vaccine for immunization will need to arrange for its purchase.

New York City

Report of Red Cross Blood Program.—The first anniversary of the Red Cross Blood Program of the Greater New York Chapter was observed May 4. The chapter reports that 5,700 patients and 202 voluntary and municipal hospitals received blood in the first year of operations of the collection program. Brigadier General Charles M. Watson, administrator, estimated that 500,000 patients were aided in municipal hospitals and through a system of individual and group credits that made blood available to 312 participating business, religious and fraternal organizations. In April 35 mobile units were sent out, and 40 are scheduled in May with visits planned to 120 business organizations.

Psychiatric Clinic to Assist Courts.—In an attempt to find basic causes of antisocial behavior in young persons brought before the city's magistrates' courts, a psychiatric clinic was opened May 2 in the Criminal Courts Building, 100 Centre Street. The clinic will be operated on a year-round basis and will be devoted exclusively to persons between the ages of 16 and 21. It is sponsored by the New York City Youth

Board, which is bearing the entire cost. Referrals will be made by magistrates and probation officers. The clinic is partly an outcome of a two month demonstration project conducted by the Youth Board jointly with the Magistrates' Courts in 1948. The board is composed of representatives of several city departments.

Teaching and Research Programs Expanded.—Dr. S. Bernard Wortis, professor of psychiatry and chairman of the department in New York University College of Medicine, has been given the additional title of professor of psychiatry and neurology in the university's new postgraduate school of medicine. He has relinquished administrative responsibility as director of the Bellevue Psychiatric Division, and on January 1 became consultant in psychiatry and neurology to the division. Dr. Lewis I. Sharp, associate professor of clinical psychiatry at New York University, has become director of the Bellevue Psychiatric Division. In addition, Dr. Morris Herrman, associate professor of psychiatry, has relinquished his position as assistant director of the Bellevue Psychiatric Division in order to do full time psychiatric teaching and research in the postgraduate and undergraduate colleges of medicine. He will be visiting psychiatrist and neurologist to the Bellevue Psychiatric Division.

NORTH CAROLINA

Tumor Clinic Opened.—Mercy Hospital in Charlotte opened a tumor clinic for charity patients February 28 with Dr. Roy B. McKnight as director. The tumor clinic is the second in Charlotte, one having been opened in the Charlotte Memorial Hospital four years ago. Doctors with patients who have tumors needing further investigation and who are unable to pay for these services may refer their patients to the clinic, which is held from 8:30 until 9:30 each Monday morning.

Dr. Lowenbach's European Assignment.—Dr. Hans Lowenbach, associate professor of neuropsychiatry, Duke University School of Medicine, Durham, has been called to active duty in the U. S. Army Medical Department as a neuropsychiatric consultant in the European Theater for one year beginning June 30. He will, among his other duties, contribute to the army's new teaching program for young army doctors abroad. Dr. Lowenbach was in Germany for seven months in 1946 as special emissary of the government.

Course in Medical Mycology.—Duke University School of Medicine and Hospital offer a month's course in medical mycology under the direction of Norman F. Conant, Ph.D., during July. The course is designed to insure a working knowledge of the human pathogenic fungi. Work with patients, cultures and laboratory animals will serve as a basis for this course. An opportunity to study gross and microscopic pathologic material will be given. Applications will be considered in the order in which they are received. An attempt will be made, however, to select students on the basis of their previous training and their stated need for this type of work. A fee of \$50 will be charged for this course, on the completion of which a suitable certificate will be awarded. Direct inquiries to Dr. Norman F. Conant, Duke University School of Medicine, Durham, N. C.

OREGON

Second Course in Nuclear Science.—The second six month course in nuclear science offered by Reed College, Portland, Ore., under sponsorship of the Atomic Energy Commission will begin July 5. The program is designed to meet the needs of postdoctoral fellows studying under the Division of Biology and Medicine of the Atomic Energy Commission, although other qualified persons may enroll. Reed is one of fourteen institutions comprising four centers in the country set up by the Atomic Energy Commission in 1948 to provide advanced training and research experience in fields relating to atomic energy. Reed, the University of Oregon at Eugene, the University of Oregon Medical School, Portland, and Oregon State College at Corvallis make up the Oregon center. Information may be obtained by writing the Atomic Energy Commission Training Program, Reed College, Portland 2, Ore.

PENNSYLVANIA

Fifty Year Practitioners Honored.—Nineteen district physicians who began practice before the turn of the century were honored by their conferees at the annual meeting of the Tenth Councilor District of the Medical Society of the State of Pennsylvania at Beaver Falls May 12. Dr. E. Roger Samuel, Mount Carmel, president-elect of the state society, presented each with a fifty year testimonial plaque. Speakers at the morning meeting included Drs. Lewis K. Sweet, Thomas

M. Leonard and Jed W. Pearson Jr., all of Washington, D. C. Dr. Chauncey L. Palmer, Pittsburgh, and Mr. Leo E. Brown, Harrisburg, spoke on what is expected of the individual physician in the American Medical Association's educational campaign aimed to defeat proposed government compulsory health insurance.

Philadelphia

Annual Lecture.—The annual lecture sponsored by the Alpha Beta Chapter of the Phi Lambda Kappa fraternity was delivered by Dr. Owen H. Wangenstein, Minneapolis, May 20 at Hahnemann Medical College. He spoke on "Studies in the Etiology of Peptic Ulcer, with Special Reference to Surgical Management."

Vaccinate Infants Against Tuberculosis.—At the request of parents, children born in the Philadelphia General Hospital are now being vaccinated against tuberculosis by means of BCG vaccine. The practice was instituted at the hospital in November 1948 and has now become an accepted procedure. Approximately 200 babies have been vaccinated. The Henry Phipps Institute of the University of Pennsylvania is cooperating with the Tuberculosis Division, Philadelphia Department of Health, in preparing the vaccine.

Pittsburgh

Pittsburgh Health Program Survey.—The U. S. Public Health Service recently made a report on a survey of the Pittsburgh Public Health Department conducted at the request of the Mayor. A team of seventeen persons headed by Dr. Erval R. Coffey, director of the Public Health Service, District 1, made the following recommendations: 1. Coordinate health programs in the communities with that of the City Department of Health. 2. Establish office of personnel and business administration and a vital records office. 3. Establish an office of public health nursing, a health education office, a nutrition office, a bureau of sanitary engineering, a dental health division and a maternal and child health division to replace the bureau of child welfare. 4. Set up a permanent tuberculosis division to expand case finding program and enlarge diagnostic follow-up clinic in the City-County Building to provide greater service to downtown residential areas. 5. Maintain a central case registry. 6. Coordinate and supervise a tuberculosis social service program and put a complete rehabilitation program in effect at Leech Farm. The survey proposed formation of the present organization into a four bureau department: administration and special services, medical services, sanitary engineering services and smoke prevention. A consultant has been assigned by the U. S. Public Health Service to help carry out the recommendations, some of which have already been put into effect.

SOUTH DAKOTA

State Medical Meeting.—The annual meeting of the South Dakota State Medical Association will be held in the Civic Auditorium, Yankton, May 22-24, under the presidency of Dr. John L. Calene, Aberdeen. Guest speakers include:

Gilbert H. Marquardt, Chicago, Diagnosis and Care of Cardiac Neurosis.
William H. Northway, San Francisco, Convalescent Care of Poliomyelitis Patients.
Edgar V. Allen, Rochester, Minn., Diagnosis and Management of Acute Peripheral Vascular Occlusions.
Frederick E. Mohs, Madison, Wis., Chemosurgical Treatment of External Cancer: A Microscopically Controlled Method of Excision.
William L. Valk, Kansas City, The Renogram, A Comprehensive Study of Renal Function.
Carl A. Moyer, Dallas, Texas, Pathologic Development Associated with Intestinal Obstructions, and Pathologic Development in Congenital Heart Disease.
James W. DuShane, Rochester, Minn., Pathologic Development in Congenital Heart Disease.
Howard B. Hunt, Omaha, Carcinoma of the Cervix.
Walter G. Maddock, Chicago, Surgery of the Biliary Tract.
Charles Crownhart, LL.D., Madison, Wis., The Cooperative Movement in Medicine.

The annual banquet will be Monday at 7 p.m. The Woman's Auxiliary to the association will meet at the Charles Gurney Hotel May 22-24.

WEST VIRGINIA

Cancer Society Gives Fund to State Department.—The West Virginia Cancer Society has appropriated \$15,000 for the treatment and care of cancer patients during the remainder of the fiscal year, to be made available to the Division of Cancer Control of the State Health Department. The society acted after failure of the State Legislature to pass a deficiency appropriation to cover the period of the last quarter of the current fiscal year. At the annual meeting of the board of directors of the West Virginia Cancer Society in March Dr. Russell B. Bailey, Wheeling, was elected chairman, Mr. Charles Lively, Charleston, secretary, and Mr. Homer Gebhardt, Huntington, treasurer.

GENERAL

Duke Alumni Dinner.—The Duke University Medical Alumni Dinner will be held at Chalfonte-Haddon Hall, Atlantic City, June 9 at 6:30 p. m. Those desiring reservations should write to Dr. Karl C. Jonas, 3401 N. Broad Street, Philadelphia 40, Pa.

Meetings in Atlantic City.—The Blood Irradiation Society will hold its annual meeting at Chalfonte-Haddon Hall June 4-5 under the presidency of Dr. Robert C. Olney, Lincoln, Neb. The American Medical Women's Association's annual meeting will be held at the Hotel Dennis, Atlantic City, June 4-5 under the presidency of Dr. Elise S. L'Esperance, New York.

Diabetes Association Meeting.—The American Diabetes Association will hold its annual meeting at the Chalfonte-Haddon Hall, Atlantic City, N. J., June 4-5. Saturday's program will be a joint session with the American Society for the Study of Internal Secretions. At the banquet Saturday evening Dr. Herbert M. Evans, Berkeley, Calif., will give the Banting Memorial Address.

O'Reilly General Hospital Reunion Dinner.—Former members of the command of O'Reilly General Hospital, Springfield, Mo., will hold a reunion dinner in the Blue Room of the Chalfonte-Haddon Hall Hotel, Atlantic City, N. J., June 8 at 7 p. m. All former members who served with Brigadier General George B. Foster Jr. at the hospital during the war are invited to be present.

Northwestern University Alumni Luncheon.—Northwestern University Medical School Alumni will meet for luncheon in the Garden Lounge of the Hotel Dennis, Atlantic City, June 8 at 12 noon. Reservations may be obtained at \$3.50 per plate either through the Medical Alumni Office, 303 E. Chicago Ave., Chicago 11, or at the booth in the alumni registration area at the convention.

Lord Horder to Give Lecture.—The annual dinner and William W. Root Address of Alpha Omega Alpha Honor Medical Society will be given on June 9 at 6:30 p. m. at the Traymore Hotel in Atlantic City, N. J. The speaker will be Lord Horder of England, founder and president of the new organization, Fellowship for Freedom in Medicine, who will speak on "Medicine and the State." Members of the medical profession and their guests are invited.

Ophthalmological Society Meeting.—The American Ophthalmological Society's annual meeting will be held at the Homestead, Hot Springs, W. Va., June 2-4, under the presidency of Dr. Bernard Samuels, New York. Among the subjects under discussion will be Simultaneous Bilateral Malignant Ocular Melanoma, Temporal Arteritis (The Horton-Magath-Brown Syndrome) as a Cause of Blindness, How Can We Best Study Primary Glaucoma? and Experimental and Clinical Use of Aureomycin in Herpes Simplex.

Inter-American Congress of Radiology.—All radiologists and those interested in radiology are invited to attend the Third Inter-American Congress of Radiology in Santiago, Chile, November 11-17. This is the first Inter-American Congress of Radiology since one convened in Havana, Cuba, in 1946. The first one took place in Buenos Aires in 1943. Those interested in attending this congress should communicate with James T. Case, M.D., Regional Secretary for the United States, 55 East Washington Street, Chicago 2, Illinois.

Nutrition Foundation Grants.—The Nutrition Foundation on May 5 authorized new grants for research totaling \$156,900. Largest of these was \$9,000 annually for three years to Dr. Frederick J. Stare, Harvard School of Public Health, Boston, for basic research on nutrition and health with special reference to hypertension. According to Mr. George A. Sloan, president, the food industry has contributed a total of \$3,400,000 in support of the foundation's work. Most of the grants made to university graduate and medical schools are in support of basic research without regard to immediate applications.

Dr. Salter Receives Award.—Dr. William T. Salter, professor of pharmacology at Yale University, New Haven, Conn., on April 27 received the first Iodine Educational Bureau Award at a meeting of the American Pharmaceutical Association. Dr. Salter was cited for his research on the relation of iodine in the blood to the thyroid gland. He was an assistant professor of medicine at Harvard, a research fellow of the Harvard Cancer Commission and associate physician at the Huntington Memorial Hospital in Boston. He has served as chairman of the Yale department of pharmacology since 1941.

Mr. Homer Sanger Dies.—Mr. Homer F. Sanger, Westmont, Ill., who was in charge of the hospital work of the Council on Medical Education and Hospitals of the American Medical Association for nearly twenty-five years, died May 6,

aged 68, after a short illness. Mr. Sanger began his work with the Council in 1919 and served until his retirement in 1943 with the exception of a short period in 1921 when he was superintendent of the Central Free Dispensary of Chicago. During his service Mr. Sanger developed the list of hospitals registered by the American Medical Association.

Kappa Delta Award in Orthopaedic Surgery.—The National Council of the Kappa Delta Sorority has inaugurated a prize of \$1,000 to be given annually by the American Academy of Orthopaedic Surgeons for the best research in orthopedic surgery performed during the year by an individual in the United States. The first award will be announced at the seventeenth annual convention of the academy in New York, Feb. 11, 1950. Those wishing to compete for this prize can secure further information from Dr. Walter Stuck, 1426 Nix Professional Building, San Antonio, Texas, chairman of the Award Committee for 1949.

Special Society Elections.—The American College of Physicians at its recent annual meeting installed Dr. Reginald Fitz, Boston, as president and chose Drs. William S. Middleton, Madison, Wis., president elect; George M. Piersol, Philadelphia, secretary-general, and William D. Stroud, Philadelphia, treasurer.—Dr. Julian G. Price of Dyersburg, Tenn., was chosen president elect of the Mid-South Post Graduate Medical Assembly at its recent meeting. Dr. Hoyt R. Allen, Little Rock, Ark., is president for 1949. Dr. Henry B. Gotten, Memphis, Tenn., who has served as secretary-treasurer for a number of years, will resign July 1, and his successor will be appointed.

W H O Given Anticholera Medal.—Sir Aly Shousha, Pasha, on behalf of the Egyptian Government presented the Egyptian Anti-Cholera Memorial Medal to the World Health Organization in recognition of the work accomplished during the late epidemic in that country. Dr. G. Brock Chisholm, New York City, director general, accepted the medal on behalf of the World Health Organization. He pointed out that, owing to the collaboration of all countries that were in a position to render assistance and to the energy of the Egyptian health authorities, the World Health Organization was able to help. Results, he said, had shown what could be accomplished by a national public health service when it was well organized and seconded by international goodwill.

Dr. Martha Eliot Resigns from Children's Bureau.—Dr. Martha M. Eliot, associate chief of the Children's Bureau, with which she has been associated for twenty-five years, has resigned to become assistant director general of the United Nations World Health Organization, effective June 1. Dr. Eliot will be responsible for the work of the Department of Operations, which includes the furnishings of experts, demonstration teams, and fellowships in the worldwide campaigns against malaria, tuberculosis and venereal disease control as well as furthering maternal and child health nutrition and environmental sanitation. Dr. Eliot, who is a graduate of Johns Hopkins University School of Medicine, Baltimore, 1918, served as United States delegate to the World Health Organization in 1948.

American Therapeutic Society.—This society will hold its annual meeting at the Chalfonte-Haddon Hall, Atlantic City, June 2-5 under the presidency of Dr. Hal McCluney Davison, Atlanta, Ga. Physicians presenting papers by invitation include:

Arnold J. Lehman, Washington, D. C., Pharmacological Evaluation of Insecticides.

Perrin H. Long, Baltimore, Impact of Sulfonamide and Antibiotic Agents on the Prognosis of Infectious Diseases.

Louis A. M. Krause, Baltimore, Biblical and Classical References to Disease.

Alfred Blalock, Baltimore, Surgical Treatment of Congenital Heart Disease.

Edwin M. Robertson, Kingston, Ontario, Canada, Treatment of Dysmenorrhoea.

Leandro M. Tocantins, Philadelphia, Physiology of Blood Coagulation.

A symposium on Factors in Blood Coagulation and Clinical Use of Anticoagulants will be held Saturday afternoon.

Survey of Allergy-Producing Molds.—An international survey this year of allergy-producing molds is being conducted by the research council of the American Academy of Allergy to determine in which areas hay fever-producing molds are most concentrated and where least prevalent. The extensive study will involve the cooperation of about fifty allergists and bacteriologists in communities in forty states, Canada and Mexico. Dr. Samuel M. Feinberg, head of the Allergy Research Laboratory of Northwestern University Medical School, Chicago, is chairman of the academy's committee on molds, which instituted the study. Scientists participating in the survey will trap air-borne molds on slides in their localities and submit the results to the central collecting agency directed by Dr. Leonard H. Harris of Northwestern University.

Dr. Dublin Named Director of Health Council.—Dr. Thomas D. Dublin, New York, has been appointed executive director of the National Health Council. The Rockefeller Foundation has made a grant of \$225,000 to the council to be used over a three year period. Under Dr. Dublin's direction the council will seek to stimulate the provision of adequate public health service of high quality. A graduate of the Harvard Medical School, Boston, and Johns Hopkins University School of Hygiene and Public Health, Baltimore, Dr. Dublin has been a member of the staff of the New York State Department of Health, and during the past six years has been professor of preventive medicine and community health at the Long Island College of Medicine, Brooklyn. He had previously taught at Johns Hopkins University Medical School and at the Albany Medical College in New York.

Dr. Avery to Receive Passano Award.—The Passano Foundation will present its \$5,000 award for 1949 to Dr. Oswald T. Avery, New York, emeritus member of the Rockefeller Institute for Medical Research, at the annual award dinner to be held at the Marlborough-Blenheim Hotel, Atlantic City, June 8. Dr. Ernest E. Irons, Chicago, President-Elect of the American Medical Association, will make one of the principal addresses. The award goes to Dr. Avery for his extensive investigations of the pneumococci, their classification, analysis, and immunologic relationships. The Passano Foundation, established by the Williams and Wilkins Company, medical publishers, Baltimore, to aid advancement of medical research, has made four previous awards. These have gone to Edwin J. Cohn, Ph.D., Harvard University, Boston, for his work on fractionation of blood; Dr. Ernest W. Goodpasture, Vanderbilt University School of Medicine, Nashville, Tenn., for virus culture by the chick embryo method; Selman A. Waksman, Ph.D., of Rutgers University, New Brunswick, N. J., for discovery of streptomycin; and last year a joint award to Drs. Helen B. Taussig and Alfred Blalock, both of Johns Hopkins University School of Medicine, Baltimore, who developed a surgical procedure for certain forms of congenital heart disease.

LATIN AMERICA

Argentine Congress of Radiology.—The newly organized Asociación Argentina de Radiología will hold its first annual meeting in July, 1949 in Santiago del Estero, Argentina. President of the association is Dr. Sabino di Rienzo, Cordoba, whose work on "Radiological Aspects of Bronchial Dynamism" was awarded first prize at the meeting of the Radiological Society of North America in San Francisco last December.

CORRECTION

Statement on the Toxicity of DDT.—In the first paragraph of the item by this title in THE JOURNAL, April 30, page 1285, the Department of the Army was inadvertently omitted from the list of agencies which took part in the conference. The Army had the principal role in the development of DDT and the representative of the Army was extremely helpful in the discussions which were summarized in the statement.

Marriages

JOHN LITCHFIELD AYER, Syracuse, N. Y., to Miss Mary-Elizabeth Lent of East Paterson, N. J., in Montclair, N. J., April 23.

HERBERT AUGUSTUS CODINGTON JR., Wilmington, N. C., to Miss Mary Littlepage Lancaster in Sumter, S. C., April 8.

ELIZABETH ANN JOLLY, San Francisco, to Mr. Thomas William Sibary of Miami, Fla., in Belmont, Calif., April 8.

CHARLES WILLIAM WILSON, Staunton, Va., to Miss Charlien Marie Simms of Dothan, Ala., March 26.

HARRY J. MANNING, Milwaukee, to Miss Joan Barbara Weinstock of Newark, N. J., March 27.

THOMAS NEUTON STERN, Memphis, Tenn., to Miss Harriet Louise Cohn of Dayton, Ohio, April 9.

HENRY CHESLEY DECKER, Richmond, Va., to Miss Margaret Reider Fisher of Baltimore, April 23.

ALAN LOUIS FRANKEL, Columbus, Ohio, to Miss Carolyn Katz in Columbia, S. C., April 12.

GERHARD ARTHUR MEYER, Flushing, N. Y., to Miss Felicitas E. Keel of New York, April 23.

Deaths

John Green * St. Louis; born in Templeton, Mass., Aug. 2, 1873; Washington University School of Medicine, St. Louis, 1898; professor of ophthalmology at St. Louis University School of Medicine; instructor in ophthalmology at his alma mater from 1909 to 1919; for many years secretary-treasurer and later chairman of the American Board of Ophthalmology; member of the House of Delegates of the American Medical Association in 1907 and chairman of the Section on Ophthalmology in 1935 and 1936; past president of the American Ophthalmological Society; vice president of the American Academy of Ophthalmology and Otolaryngology, 1917-1918 and the St. Louis Medical Society in 1927; member of the Association for Research in Ophthalmology; fellow of the American College of Surgeons; formerly member of the board of health; from 1910 to 1920 member of the board of education in University City, Mo.; on the staffs of St. Louis County Hospital in Clayton, De Paul, Firmin Desloge, St. Louis City, St. Luke's and St. Mary's hospitals; for many years associated with Barnes and St. Louis Children's hospitals; formerly secretary of the city's Joint Medical Council; director of the St. Louis Mutual Life Insurance Company; at one time secretary and president of the Medical Society of City Hospital Alumni; died April 7, aged 75.

Hampton Pharr Cushman * Detroit; born in Milton, La., July 16, 1894; Vanderbilt University School of Medicine, Nashville, Tenn., 1915; associate professor of clinical gynecology and obstetrics at the Wayne University College of Medicine; extramural lecturer in gynecology at the graduate school of medicine at the University of Michigan, Ann Arbor; specialist certified by the American Board of Obstetrics and Gynecology; member of the Central Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; served in France during World War I; during World War II a member of the procurement and assignment board of physicians; on the staffs of the City of Detroit Receiving Hospital, Florence Crittenden Hospital and Harper Hospital, where he died February 13, aged 54, of myocardial infarction.

Charles Ogilvy * New York; born in Montreal, Sept. 1, 1874; McGill University Faculty of Medicine, Montreal, Canada, 1898; formerly on the faculty of the New York Post-Graduate Medical School and Hospital; certified by the American Board of Orthopaedic Surgery; member of the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; served during World War I; on the staffs of the New Rochelle (N. Y.) Hospital, White Plains (N. Y.) Hospital, United Hospital in Port Chester, Nassau Hospital in Mineola, Professional Hospital in Yonkers and Grasslands Hospital in Valhalla; died February 18, aged 74.

Wilford Anderson Hall Councill * Baltimore; born in Mathews, Va., Jan. 30, 1891; University of Maryland School of Medicine, Baltimore, 1914; specialist certified by the American Board of Urology, Inc.; member of the American Urological Association; fellow of the American College of Surgeons; served during World War I; associate in genitourinary surgery at his alma mater; instructor in urology at the Johns Hopkins University School of Medicine; affiliated with University, Johns Hopkins, Maryland General and Franklin Square hospitals; died in Palm Beach, Fla., March 26, aged 58.

David Alexander, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; at one time on the faculty of his alma mater; died January 13, aged 84, of chronic myocarditis.

Eugene Argo, Goodwater, Ala.; University of Nashville (Tenn.) Medical Department, 1891; Vanderbilt University School of Medicine, Nashville, Tenn., 1891; member of the American Medical Association; died February 16, aged 80, of heart disease.

Bion Arnold, Belleville, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1889; died February 2, aged 88, of cerebral hemorrhage, hypostatic pneumonia and arteriosclerosis.

Walter Carter Ayles, Auburn, Wash.; Vanderbilt University School of Medicine, Nashville, Tenn., 1915; member of the American Medical Association; formerly associated with the Indian Service; served as health officer; died February 24, aged 58, of heart disease.

Albert J. Bennett, Chicago; National Medical University, Chicago, 1902; died February 16, aged 71.

Marietta Helen Bewley, Los Angeles; University of Southern California School of Medicine, Los Angeles, 1900; member of the American Medical Association; formerly examining physician in Juvenile Court and on the lunacy commission of Los Angeles County General Hospital; affiliated with the Hollywood, California and Queen of Angels hospitals; died February 14 aged 75, of melanotic sarcoma.

Robert Gray Bond, Harrisburg, Ill.; St. Louis College of Physicians and Surgeons, 1909; member of the American Medical Association; died in San Diego, Calif., February 27, aged 70, of carcinoma of the stomach.

Charles Haskell Bowers, Baltimore; Johns Hopkins University School of Medicine, Baltimore, 1945; served during World War II; resident in the department of pathology at the Johns Hopkins Hospital; certified by the National Board of Medical Examiners; died in the Johns Hopkins Hospital February 21, aged 28, of homologous serum jaundice with acute yellow atrophy.

Sidney Leonard Brown, San Francisco; Indiana University School of Medicine, Indianapolis, 1948; intern at San Francisco Hospital; died February 4, aged 24, of pneumonia.

Edgar Clough Buck, Newport, Ky.; Pulte Medical College, Homeopathic, Cincinnati, 1891; died in Speer's Memorial Hospital, Dayton, February 12, aged 79, of lobar pneumonia.

Raymond Alfred Butler * Beech Grove, Ind.; Indiana University School of Medicine, Indianapolis, 1908; served overseas during World War I; formerly on the staff of St. Francis Hospital, where he died February 25, aged 64, of nephrosclerosis.

P. B. Carrigan, Hope, Ark.; Missouri Medical College, St. Louis, 1899; died February 22, aged 76.

Joseph Gibson Clemons, Mount Orab, Ohio; Starling Medical College, Columbus, 1892; died in Christ Hospital, Cincinnati, February 22, aged 81, of a fracture of the right femur and myocardial failure.

Herman Harrison Cole * Springfield, Ill.; University of Michigan Medical School, Ann Arbor, 1917; past president of the Sangamon County Medical Society and past vice president of the Illinois State Medical Society; served as president of the Central Illinois District Medical Society; served during World War I; on the staffs of Memorial Hospital and St. John's Hospital, where he died February 16, aged 55, of coronary occlusion.

Thomas Francis Cook * Richmond, Mo.; St. Louis University School of Medicine, 1918; for many years secretary-treasurer of the Ray County Medical Society; member of the school board; for six terms county physician; served during World War I; member of the staff of the Research Hospital in Kansas City; examiner for draftees of World War II; died February 6, aged 56, of coronary occlusion.

Charles Spencer Crandall, Utica, N. Y.; University of the City of New York Medical Department, New York, 1882; died February 18, aged 90, of arteriosclerosis.

Ernst Ostergaard Dahl, Brookline, Mass.; Københavns Universitet Laegevidenskabelige Fakultet, Denmark, 1921; died in Tucson, Ariz., February 8, aged 53, of peptic ulcer with hemorrhage.

Edward Maze Dance, Lowell, Ark.; Vanderbilt University School of Medicine, Nashville, 1880; died in City Hospital, Fayetteville, January 28, aged 91, of carcinoma of the prostate with metastases.

Murray Sayle Du Mont * Mount Morris, Ill.; University of Illinois College of Medicine, Chicago, 1933; affiliated with Rockford (Ill.) Memorial Hospital; died February 28, aged 42, of carcinoma of the pancreas.

John Joseph Egan, Waterbury, Conn.; University of Maryland School of Medicine, Baltimore, 1907; member of the American Medical Association; served during World War II; formerly affiliated with the Veterans Administration; served as police and fire surgeon; on the staffs of Waterbury and St. Mary's hospitals; died in Veterans Administration Hospital, Newington, February 1, aged 65, of pulmonary tuberculosis.

Walter Ernest Fine * Ambler, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1904; died February 28, aged 70, of coronary disease.

Harley Bruce Fisk, Miami, Fla.; Ohio-Miami Medical College of the University of Cincinnati, 1915; chief medical officer for the regional office of the Veterans Administration; died in Coral Gables (Fla.) Hospital, February 11, aged 58, of coronary occlusion and pulmonary embolism.

Eldred Eadie Fraser ☉ Detroit; Detroit College of Medicine and Surgery, 1930; for many years on the staff of the Grace Hospital; died February 26, aged 45, of coronary thrombosis.

Homer Elmer Fraser ☉ New Lebanon, N. Y.; Bellevue Hospital Medical College, New York, 1891; an Affiliate Fellow of the American Medical Association; fellow of the American College of Surgeons; formerly on the faculty of the Long Island College of Medicine in Brooklyn, where he was on the staffs of the Kings County Hospital, Brooklyn Hospital and Caledonian Hospital; died in the House of Mercy Hospital, Pittsfield, Mass., February 17, aged 88, of coronary occlusion.

Claude Wesley Freeman, Los Angeles; University of Toronto Faculty of Medicine, Toronto, Canada, 1903; died February 6, aged 75, of acute myocardial failure.

Arthur Alfred Fuhlbrigg, Des Plaines, Ill.; University of Nebraska College of Medicine, Omaha, 1931; member of the American Medical Association; on the staff of the Lutheran Deaconess Home and Hospital in Chicago; died February 21, aged 48, of coronary thrombosis and arteriosclerosis.

William F. Goetze, St. Joseph, Mo.; Medical College of Ohio, Cincinnati, 1890; member of the American Medical Association; died January 30, aged 87.

Sidgel Fred Gregory, Bradfordsville, Ky.; Kansas City (Mo.) University of Physicians and Surgeons, 1929; served overseas during World War I; died in St. Joseph's Hospital, Louisville, February 4, aged 55, of bilateral infarcts of the kidney, multiple abscesses of the pancreas and bronchopneumonia.

Theodore Everett Hardy, Waterville, Me.; Harvard Medical School, Boston, 1932; member of the American Medical Association and the New England Obstetrical and Gynecological Society; served during World War II; Colby College physician and athletic physician; on the staff of the Thayer Hospital; died February 11, aged 43.

Don Villette Hargrave, Eaton Rapids, Mich.; Detroit College of Medicine, 1913; health officer; died in Lansing, February 24, aged 62, of Landry-Guillian-Barré disease.

Walter Handy Janney, Alexandria, Va.; University College of Medicine, Richmond, 1900; affiliated with Alexandria Hospital, where he died January 3, aged 74, of retroperitoneal hemorrhage and arteriosclerosis.

John Alexander MacKenzie, Milwaukee; Manitoba Medical College, Winnipeg, Manitoba, Canada, 1916; associate clinical professor of ophthalmology at Marquette University School of Medicine; died February 27, aged 57, of acute coronary occlusion.

John Willis Meachen ☉ Boston; Harvard Medical School, Boston, 1922; member of the New England Roentgen Ray Society; specialist certified by the American Board of Radiology; affiliated with Emerson Hospital in Concord and Massachusetts Womens Hospital; died February 24, aged 56, of arteriolar nephrosclerosis, hypertension, pericarditis and diabetes mellitus.

Eugene Lawrence Morgan, Phillipsburg, Kan.; University Medical College of Kansas City, Mo., 1906; formerly mayor; at one time represented Phillip County in the state legislature; died in Concordia, recently, aged 68, of pulmonary embolism, following an injury received in a fall.

Luther A. Mott, Elwood, Ind.; Pulte Medical College, Homeopathic, Cincinnati, 1900; on the staff of Mercy Hospital; died February 7, aged 77, of cerebral hemorrhage.

Winfield Scott Nay ☉ Underhill, Vt.; University of Vermont College of Medicine, Burlington, 1873; an Associate Fellow of the American Medical Association; for many years secretary of the Vermont State Board of Medical Registration; died in Mary Fletcher Hospital, Burlington, January 16, aged 98.

Milton Oscar Nyberg, Wichita, Kan.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1913; formerly secretary of the state board of health; at one time health officer of Ashland; served during World War I; died in Wesley Hospital February 4, aged 61, of coronary thrombosis.

Sherman Elmer Grant Pedigo, Athens, Ohio; Starling Medical College, Columbus, 1895; served during World War I; on the staff of Sheltering Arms Hospital; died January 21, aged 78, of strangulated femoral hernia.

W. N. Pierce, Little Rock, Ark. (licensed in Arkansas in 1903); died February 25, aged 83, of a fractured right femur and cardiorenal disease.

Samuel Madden Pierre, Washington, D. C.; Howard University College of Medicine, Washington, D. C., 1893; died in Emergency Hospital February 19, aged 76, of carcinoma of the prostate and coronary thrombosis.

Robert Earl Pound ☉ New York; University of Virginia Department of Medicine, Charlottesville, 1916; specialist certified by the American Board of Radiology, Inc.; member of the American Roentgen Ray Society and of the American College of Radiology; served as secretary and as trustee of the New York Academy of Medicine; an officer in France during World War I; affiliated with Lawrence Hospital in Bronxville; died in the New York Hospital February 6, aged 55.

Leon E. Reynolds, St. Petersburg, Fla.; University of Pennsylvania Department of Medicine, Philadelphia, 1886; for many years practiced in Belgrade, Me.; died February 16, aged 84, of angina pectoris.

Joseph Walker Roberts, Philadelphia; Howard University College of Medicine, Washington, D. C., 1907; died February 10, aged 69, of lobar pneumonia.

Grant Emerson Royce, Sparland, Ill.; Northwestern University Medical School, Chicago, 1927; died February 3, aged 45.

James G. Sandidge, Mulberry, Kan.; Missouri Medical College, St. Louis, 1893; member of the American Medical Association; for many years affiliated with Mount Carmel Hospital; died February 6, aged 78, of arteriosclerosis.

Thomas M. Sanford, Lansing, Mich.; Barnes Medical College, St. Louis, 1894; died January 30, aged 84, of coronary sclerosis.

Eugene Joel Schachter ☉ Pittsburgh; Indiana University School of Medicine, Indianapolis, 1926; school physician; served on the staffs of the Braddock (Pa.) General Hospital and Montefiore Hospital; died February 3, aged 47, of acute heart disease.

Laurence Roland Serrurier ☉ Portland, Ore.; University of Oregon Medical School, Portland, 1927; specialist certified by the American Board of Internal Medicine; member of the American Psychiatric Association, Oregon Neuro-psychiatric Society and the North Pacific Society of Neurology and Psychiatry; medical director of Morningside Hospital, where he died January 31, aged 49, of coronary thrombosis.

Marvin Smith, Lebanon, Ill.; University of the City of New York Medical Department, New York, 1883; member of the American Medical Association and the Connecticut State Medical Society; died in St. Elizabeth's Hospital, Belleville, January 30, aged 88, of cerebral arteriosclerosis.

Roscoe Franklin Snyder, Kalamazoo, Mich.; College of Medicine and Surgery (Physio-Medical) Chicago, 1901; member of the American Medical Association and the Kalamazoo Academy of Medicine; on the staff of Borgess Hospital; died February 2, aged 74, of hypertensive cardiovascular disease.

Frank Roy Steelsmith ☉ Des Moines; Drake University Medical Department, Des Moines, 1901; died February 5, aged 74, of coronary thrombosis and prostatic carcinoma.

Edwin Luther Stevens ☉ Penny Farms, Fla.; Northwestern University Medical School, Chicago, 1892; member of the Illinois State Medical Society; at one time professor of diseases of children at the Drake University College of Medicine, Des Moines; served on the staffs of St. Joseph's and Sherman hospitals in Elgin, Ill.; died in Jacksonville, January 16, aged 79, of lung abscesses.

Thomas Boyd Turner, Stigler, Okla.; University of Nashville (Tenn.) Medical Department, 1898; for many years county health officer; died February 19, aged 81, of cerebral thrombosis and arteriosclerosis.

Marshall W. Weir ☉ Oklahoma City; Washington University School of Medicine, St. Louis, 1906; affiliated with Wesley Hospital, where he died February 4, aged 75, of myocardial infarction.

Herbert Elmer Woelfel ☉ Bellevue, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1908; on the staff of Suburban General Hospital; died February 13, aged 66, of coronary thrombosis.

Alexander Graham Wooldridge, Butler, Mo.; Washington University School of Medicine, St. Louis, 1932; member of the American Medical Association; president of the Bates County Medical Society; formerly county coroner; served during World War II; on the staff of Butler Memorial Hospital; died January 26, aged 42, of coronary occlusion.

Foreign Letters

BELGIUM

(From Our Regular Correspondent)

LIÈGE, April 18, 1949.

Pathology of the Pancreas

The second Belgian Congress of Surgery held an extraordinary session with the Belgian Society of Gastroenterology and discussed the important question of the pathology of the pancreas. E. Van Campenhout and M. Duperroy presented data concerning the pathologic anatomy of the pancreas. J. La Barre and P. Houssa devoted their report to the physiologic basis of the pathologic changes in the endocrine and exocrine functions of the pancreas. A. Froehlich and R. Crismer reported on biochemical concepts of pancreatic disorders. J. Jeanmart has made a thorough study of the radiology of the pancreas, and concluded that disorders of the pancreas still find the radiologist almost completely unprepared. Nevertheless, the radiomanometry practiced by Mallet-Guy and by Caroli seems to justify great hopes. J. De Witte discussed the etiopathogenesis, the diagnosis and the medical treatment of acute disorders of the pancreas. The treatment must be medical in the acute phase. However, in case of doubtful diagnosis and in case of evident involvement of the biliary passages or in case the medical treatment is ineffective surgical exploration is indicated. Two mechanisms apparently may lead to the production of pseudocysts of the pancreas: necrosis and hemorrhage. G. de Busscher spoke on the symptoms and the medical treatment of chronic disorders of the pancreas.

J. Cahen devoted his report to surgery. He took up the acute forms of pancreatitis, pseudocysts of the pancreas, chronic pancreatitis, pancreatic lithiasis, contusions of the pancreas and the surgery of cancer of the pancreas and of the ampulla of Vater. The author indicated that local exeresis of the ampulla has a surgical mortality of 30 to 35 per cent. It results in a certain number of prolonged survivals, rarely beyond three years; the percentage of these is so small that it can hardly be determined. Since 1935, it has been replaced by pancreatoduodenectomy, which responds better to the concept of the surgical treatment of cancer. This serious intervention has a surgical mortality of about 30 per cent. It does not appear possible as yet to establish the percentage of prolonged survival. In these conditions the author does not feel that it is possible to decide definitely in favor of the one or the other of these two operations on the ampulla of Vater. René Goffin discussed the question of hyperinsulinism.

Summarizing, the chairman, Dr. George De Busscher, drew conclusions from this important discussion. The regulation of the sugar metabolism is disturbed in the course of diabetes of Langerhans, of alloxan diabetes, of the diabetes of Young (by injection of increasing doses of extract of the entire anterior lobe of the hypophysis) and of diabetes by disturbance in the mechanism of the nervous regulation of the sugar metabolism. There is a certain degree of dependence between the external and internal functions of the pancreas. Aspiration of the pancreatic juice is made best by the double tube of Agren-Lagerlof, before and after the intravenous injection of purified secretin alone or associated with acetyl-beta-methylcholine. Acute pancreatitis can be inflammatory without causing necrosis or hemorrhage by inducing edema; it develops in the course of an infectious process and its treatment is anti-infectious. Acute necrotic pancreatitis is characterized by necrosis of the parenchyma, edema, hemorrhage and steatonecrosis, or by one or several of these lesions. The pathogenic elements are the following: biliary factors (cholecystitis, cholelithiasis, dyskinesia of the biliary passages), neurovascular or anaphylactic factors.

The etiopathogenesis of chronic pancreatitis is not clarified: Fibrosis of the pancreas seems to be a result of the extravasation of pancreatic juice without corrosion of the blood vessels. Chronic recurrent pancreatitis constitutes a succession of sublethal attacks of acute interstitial pancreatitis or of hemorrhagic pancreatitis or perhaps a combination.

Preoperative roentgenologic exploration of the biliary passages constitutes a great advance in the radiologic field in recent years. If the diagnosis of pancreatitis is established, medical treatment will be instituted. It may eventually be followed by surgical intervention, but every case requires individualization. If the diagnosis is not sure, a laparotomy is indicated. The pseudocysts will be treated by marsupialization or by cystoanastomosis, if possible. In the course of pancreatic lithiasis removal of the calculus, biliary drainage, hemipancreatectomy on the left side, total pancreatectomy and cephalic duodenopancreatectomy find their special indications.

Surgery of diabetes must be reserved for the cases of grave insulin-resistant disease with fatal prognosis, for cases aggravated by a complication in other organs such as exophthalmic goiter, adrenal or hypophysial tumors and in which interventions on these organs are likely to improve the complex sugar regulation.

Medical Service in the Belgian Congo

The report on the health conditions in the Belgian Congo during the year 1946 has been published. The Governmental Medical Service at the end of 1946 comprised 211 physicians, 4 pharmacists and 223 health agents. It is necessary to add to this 99 physicians of industrial organizations, 40 physicians of missions and philanthropic organizations, 18 private physicians, 13 dentists, 12 pharmacists and numerous health agents (more than 100). There are between 300 and 400 nurses (religious and others) and numerous native personnel. The budget of the Governmental Medical Service for 1946 exceeds 227,000,000 francs; the expenditures are not known as yet (the budget for 1936 was around 75,000,000 francs).

Concerning the health of the natives, we learn that in 1946, in all the government agencies, 1,500,000 natives were treated, with 7,800 deaths. Besides these, in mobile units and missions and philanthropic organizations 18,000 cases of trypanosomiasis were treated, 215,000 cases of yaws, 56,000 of leprosy, 55,000 of syphilis and 2,500 of tuberculosis.

In an interview published in the *Cape Times* M. J. G. Garinus, Governor of the Province of the Cape of Good Hope, said, "The Government of the Belgian Congo considers the health of the natives as one of the very first responsibilities which it has to face." He then described all the efforts made in the construction of health establishments and concluded: "South Africa can certainly learn from the initiative of the Belgian Congo, without losing sight of the fact that the problem of the medical service of the natives cannot be considered completely identical in the two countries." Regarding congenital malaria and on the basis of an intensive study by the Belgian Society of Tropical Medicine, a committee has been created to condense the results of the study. The committee has confirmed the absence or at least the extreme rarity of congenital malaria in natives in the endemic regions of Central Africa.

Congress of Sickness and Accident Insurance

The first International Congress of Medical Insurance organized by the Belgian Medical Society for the study of sickness and accident insurance was held in Brussels and in Spa. The history of sickness and accident insurance was presented by Dr. Casman, who outlined the role of the physician counselor. The task of this counselor is immense; he must make an exact diagnosis in complicated cases. To fulfil this task he has at his disposal all modern technics, and he can ask the opinions

of the most eminent specialists. The physician counselor must also be interested in the social conditions of the patient and look after his material well-being. He must, in certain cases, advise the patient to take up a new occupation. To do this, he must give occupational aptitude tests and assign the patient for reorientation and new training. This difficult task can be carried out only in close cooperation with the attending physician, and it is he who must do more and more in this respect.

University Sanatorium

After the war, when the conditions of hospitalization were clearly insufficient in Belgium, numerous Belgian students who had tuberculosis were evacuated to Leysin in Switzerland. Soon the idea was conceived of grouping all these students together in Belgium, and the University Sanatorium of Eupen was established. On Oct. 9, 1947, the first students were hospitalized there. At this time, 71 patients are under treatment, of whom 48 are students and 23 are intellectuals. A medical director, an assistant physician, 6 nurses and numerous other personnel maintain the service. The ceremony of inauguration was held in the presence of her Majesty the Queen and other important persons. In the course of this ceremony President DeVleeshouwer indicated that all Belgian students should unite to participate in the realization of the project so that the sanatorium can fulfil all the hopes held for it.

Quinine in the Belgian Congo

Bruxelles-médical gives an account of a study which M. E. H. J. Stoffels has published on the subject of quinine. In Kivu planted stocks in normal conditions no longer exist. Stoffels is of the opinion that a plantation of 1 hectare with 12,345 trees can produce the following quantities of quinine, expressed in kilograms of sulfate of quinine: third year (prunings) 28.2 Kg.; fourth year, 43.4 Kg.; fifth year, 48 Kg.; sixth year, 81 Kg.; seventh year, 72 Kg.; eighth year, 80 Kg.; ninth year, 120 Kg.; tenth year, 160 Kg.; eleventh year, 200 Kg., and twelfth year, 320 Kg., a total of 1,152.6 Kg. of sulfate of quinine extracted from 14,450 Kg. of bark; that is, an average content of 8 per cent.

TURKEY

(From Our Regular Correspondent)

ANKARA, Feb. 22, 1949.

Tenth National Medical Congress

Under the auspices of Ismet İnönü, President of Turkey, and with Hasan Saka the Prime Minister as honorary president, the tenth medical congress was held at Ankara October 4-7; it was attended by more than six hundred members from all parts of the country. As usual the congress was accompanied with an exhibition of domestic and foreign pharmaceutical preparations and public health propaganda. Dr. Kemali Bayizit, the Minister of Health and Social Assistance, opened the congress. The two main themes were industrial hygiene and thyroid diseases in Turkey. Until 1929 the Ministry of Health and Social Assistance was responsible for maintaining the health of workers. With the enactment of the labor law in 1936 all matters pertaining to workers and the application of the labor law became the responsibility of the Ministry of Economics. The rapidly increasing number of workers brought about by the industrialization of the country resulted in the establishment of the Ministry of Labor in 1946. The main divisions are the division of health, the division of workers in industry and the division of workers' insurance. Laws and regulations pertaining to working hours and compensation have been enforced; workers' syndicates and workers' infirmaries and hospitals have been established, and accident and disablement compensation and matters pertaining to maternal and child health have been

fixed. Establishments employing more than 50 workers must have an infirmary and a physician; those employing more than 500 must have a hospital, a surgeon and a medical specialist. At present there are almost 400,000 skilled workers in different industries. A motion was carried that industrial hygiene be added to the list of medical specialties, of which there are now twenty-four: internal medicine, tuberculosis, general surgery, neurosurgery, obstetrics and gynecology, bacteriology and infectious diseases, parasitology, ophthalmology, otorhinolaryngology, pediatrics, dermatology and venereal diseases, psychiatry and neurology, radiology and radiotherapy, urology, orthopedics, stomatology and stomatology plastics, biochemistry, pharmacodynamics, pathology, legal medicine, hygiene and preventive medicine, physical culture and school hygiene, public health, and hydrology and physical therapy.

On the second day of the congress diseases of the thyroid were discussed. The principal localities where goiter is endemic in Turkey are Isparta, Bolu, Kastamonu, Adapazar and the Bozkir and Ermanak districts of the Konya province. The town of Isparta is well known for its many young girls and women afflicted with goiter. In the Kastamonu Ilgaz mountain region the goiter incidence is noticeably higher. According to veterinaries goiter is also encountered in animals grazing in that region. In Afyon, Amasya, Erzurum, Geyve and Duzce goiter is occasionally seen. In Denizli, a province of more than 300,000 inhabitants, only in 1 woman has colloid goiter been encountered in three years, and among the 13,000 patients examined in the hospital of Hatay there were only 2 cases of toxic diffuse goiter and 2 cases of struma. Among the 2,200 patients admitted during the last six years to the Diyarbakir Model Hospital surgical department there were only 15 cases of goiter and 2 of toxic diffuse goiter. But in the mountainous Zonguldak Black Sea region 12 adenomatous toxic, 23 cystic, 25 nodulous, 62 parenchymatous and 3 cancerous strumae have been encountered; 2.3 per cent were toxic diffuse goiters, and 91 per cent of the patients with goiter were women. For the last three years the inhabitants of the goiter regions have been supplied with iodized salt, and goiter posters and pamphlets have been distributed. Generally speaking, the goiter situation in Turkey is not serious.

Dr. Ziver Mestci of the Trabzon Model Hospital submitted a report on the 248 patients with struma admitted to his department for operation. Of the 248 patients, 164 were women and 84 were men; of 95 patients with toxic diffuse goiter, 66 were women and 29 were men. Age groups were as follows:

Struma		Toxic Diffuse Goiter	
Age, Years	Percentage	Age, Years	Percentage
10-19	15.3	10-19	7.4
20-29	21.3	20-29	32.5
30-39	26.6	30-39	44.3
40-49	26.1	40-50	12.8
50-60	10.7		

Three of the 248 patients with struma and likewise 3 of the 95 patients with toxic diffuse goiter did not recover after operation; on admission they were weak and anemic and the disease was far advanced.

The eleventh medical congress is to be held in 1950 at Ankara. The topics will be tuberculosis in Turkey and tuberculosis control, the surgical treatment of tuberculosis and bone and joint tuberculosis. On the occasion of the national medical congress the fifth surgical, the third gynecologic and second microbiologic congresses were also held in Ankara. At the tenth medical congress almost one hundred papers were submitted; at the gynecologic congress 57 were presented.

Council on Medical Education and Hospitals

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

Forty-Fifth Annual Meeting, Held in Chicago Feb. 6, 7 and 8, 1949

FEBRUARY 7—MORNING

DR. HERMAN G. WEISKOTTEN, Syracuse, N. Y., Presiding
New Medical Schools

DR. HERMAN G. WEISKOTTEN, Syracuse, N. Y.: This paper was published in *THE JOURNAL*, May 7, page 8.

Medical Education in Programs of the Public Health Service

DR. LEONARD A. SCHEELE, Washington, D. C.: This paper was published in *THE JOURNAL*, May 7, page 5.

The World Medical Association and Medical Education

DR. LOUIS H. BAUER and MARGARET L. NATWICK, A. M., New York: The World Medical Association was organized in Paris in September 1947. At present thirty-nine countries are members and applications are pending from several others. The objects of the association are to effect better liaison among the doctors of the world, to organize a medium of exchange, to study and report on the problems confronting the medical profession, to represent world medical opinion before international bodies, to assist all peoples of the world to attain the highest level of health and to promote world peace. Not all nations have a truly representative medical association, which is why some countries are not represented. It seems to be a definite fact that where there is no strong national medical association, medical care and medical education are on a distinctly lower plane. In the second General Assembly, held last September at Geneva, among the many momentous decisions made were:

1. Appointment of a committee to draft an International Code of Ethics.

2. Adoption of a report on "The Status of the Medical Profession in 23 Countries." This report covers medical man power, registration of physicians, professional organizations, the environment of medical practice, the trend of medical practice and the status of the doctor in all these countries.

3. Adoption of a report on Social Security and Health Insurance, including twelve principles, wherever medical care is provided as a part of social security.

4. Preliminary consideration of methods of coordinating the medical press of the world. Decision to publish a quarterly *Bulletin* on the activities of the association.

Other matters considered at the Assembly, and which are now engaging the activities of the Secretariat are:

1. The Advertisement and Sale of Secret Remedies and Appliances.

2. "Unqualified Medical Practice." The report covers the regulations governing cult practice, whether or not such practices are growing, and the nature of schools of training, if any. It is a matter of regret that the United States is one of a very few countries where there are schools or programs of training for unqualified practitioners.

3. Postgraduate Training and the Training of Specialists.

For some time now the Association has been engaged in the Study of Undergraduate Medical Education, and the study is now nearly complete. It covers information as to the medical schools of twenty-six countries. It is hoped to keep this study up to date. Such a study has never been done before. It is believed that the World Medical Association, by publishing such a report and through its member associations can be of great assistance in bringing about a uniform high standard of medical education throughout the world.

Very few of the activities of the World Medical Association would be possible without the assistance of the United States Committee. The United States Committee was incorporated as a nonprofit organization to give financial support to the World Medical Association. The Committee agreed that, if the headquarters of the Association were established in North America, it would guarantee the financial support up to a certain limit of the Secretariat, publication of the *Bulletin* and

the cost of the traveling expenses of members of the Council in attending official meetings, as otherwise some of them would not be able to attend. The headquarters have been established in New York City. Membership in the Committee is open to all organizations and individuals. Medical associations, organizations allied to medicine, semiprofessional organizations and many individuals are contributing financial support to the promotion of world medicine, world health and world peace. We hope that at least 5,000 doctors become members of the committee.

The potentialities of the association are boundless, if we succeed in obtaining the proper financial assistance. All doctors should assist in the work of raising and unifying the standards of public health, medical education and medical care throughout the world. Doctors of the world have a common meeting ground, and through them and their influence a better understanding among nations can be obtained.

DISCUSSION

DR. DONALD G. ANDERSON, Chicago: During the past two or three years particularly there has been a great need for knowledge in this country of medical education programs abroad. Many physicians who have received their training in foreign countries are eager to come to the United States and to enter practice. The state licensing boards, therefore, need accurate information about the institutions in which these men received their training. A small group, which will probably grow larger, of American citizens who wish to go abroad to receive medical training and then return to this country to practice also need information. There is also the possibility that the exchange of students between medical schools and possibly even an exchange of instructors may develop as we come to know more about the facilities and institutions in other countries. During these past two or three years, while this need has been becoming evident, a number of groups have been trying to gather some of this information. It seems likely that with this entrance of the World Medical Association into this field we may be able to get the information which is now being sought from many quarters in this country.

Utilization of Regional Hospitals for Medical Education

DR. CHARLES F. WILKINSON JR., Battle Creek, Mich.: In the past several years many schools have adopted an attitude that the justification for their existence is dependent not only on their turning out well equipped physicians, but also on their ability to keep the physicians in their realm of influence informed as to recent developments in diagnosis and treatment. This brings to mind an entirely different institution from that commonly envisaged when the term medical school is used. This trend is seen not only in tax-supported schools, for many advances in continuation technic and much of this philosophy of regional obligation have developed in privately endowed medical schools.

A hospital functions effectively in discharging its obligation largely in proportion to its activities in the field of medical education. During the past several years many attempts have been made to integrate the local hospital as an educational institution with the medical school as the center of regional medical education. For a time I was intimately involved in the program at the University of Michigan that attempted to do this. The need of hospitals for many of the things to be found only at a university center was equalled by the need of the university for the hospital's space and staff in the training of interns and residents. As a result a program was developed which it was hoped would not only give good intern and resident training in hospitals distant from the medical school, but would also serve as a daily stimulation to the continuing education of physicians practicing in areas served by those hospitals. Certain broad principles served to set the course of this program and they are believed to hold true in the continuous education of any physician: 1. Medical schools can no longer hope to prepare a person for the practice of medicine for more than four or five years after graduation. 2. A physician can continue his own education, but this is not likely to be the most efficient method by which his skill can be maintained. 3. A medical school's primary obligation is to the undergraduate, but scarcely less important is its obligation of educating residents and practicing physicians. 4. This is especially true of tax-supported institutions

in their relation to the practicing physician. 5. A medical school's influence should, wherever possible, be carried to the physician, as well as offering more formal training on the campus. 6. Short courses are valuable but do not obviate the need for planned day by day stimulation. 7. The best place for this day by day stimulation is in the hospital where the physician practices. 8. Ideally, the practice of medicine should be made up of three components: (a) the care of the sick; (b) teaching of undergraduates, residents or other physicians, and (c) some type of investigative work.

The foregoing definition for the ideal practice of medicine is open to some criticism. Certainly the physician of today should be acutely aware of preventive medicine, and I agree with my critics that the care of the sick should be broadened to include the prevention of disease.

A hospital that desired to affiliate approached the university and was visited by the coordinator of the decentralized program. They were acquainted with the basic teaching requirements of the program which were: 1. Teaching ward rounds conducted daily. 2. Roentgenologic conferences in each affiliated service weekly. 3. Clinical-pathologic conferences which may alternate between medical and surgical cases weekly. 4. Clinical conferences by the medical service, and clinical and necropsy review conferences by the surgical services. 5. Responsibility during the surgical resident's fourth year for a fifteen to twenty bed ward or its equivalent. 6. Each chief of service was either a certified specialist or a fellow of his respective board or college. When this requirement could not be fulfilled, a member of the staff with these requirements could be selected from the service to act as preceptor. In addition the university sent members of the senior faculty to the affiliated hospitals to participate in ward rounds and conferences once each month in medicine and surgery. During the third year out of medical school, or the second year in specialty training, the resident came from the affiliated hospital to the University of Michigan to spend either a year or nine months in the study of the basic sciences closely correlated with clinical application. During this period, approximately two fifths of the resident's time was spent in clinical application, while the remainder was spent in the basic science departments.

There were a number of difficulties that were unique to the programs at the University of Michigan, or at least, appeared to be. All of the schools engaged in such programs have their troubles. I know of no such program that is as good as it was planned to be. These inherent faults are important, but they are not as significant as are the advantages. Intern and resident training has become too complex to be considered merely as a work experience. It is part of the physician's education, and should be under the supervision of medical schools. The medical school alone cannot assume the responsibility for training all residents within its walls. It can, however, through affiliation with regional hospitals, expand the number of residents for whose education it is responsible and at the same time participate in a truly regional medical educational program.

DISCUSSION

DR. CURRIER McEWEN, New York: Like the one described, our program at New York University has been made possible by the support of the W. K. Kellogg Foundation. Ours started in September 1947, and the leading spirit in setting it up has been Dr. Clarence de la Chapelle. When, during this last year, the new Postgraduate Medical School was established as a part of the New York University-Bellevue Medical Center, this regional hospital program carried over into the program of the Postgraduate School, and we now look on it as one of the most interesting experimental projects of that school. We have ten participating hospitals as compared with fifteen in Michigan. During the shorter period that ours has been in progress, we have had twenty-three residents enrolled as compared with their seventy-five. Our hospitals rank in size from one hundred to eight hundred beds and they are in communities of 2,000 to 58,000 population. They are in an area within 100 miles of New York City. We believe that this type of program offers the unique opportunity for community service, and at the same time one for expansion of graduate and postgraduate teaching through the participation in the training of the residents and the attending staffs also in these outlying hospitals. We

hope also that eventually, on an elective basis, undergraduate students will take part in the program, that they at least will go out and work in these hospitals and in this way widen their experience through a type of service in suburban and rural areas, which of course is so different from that experience they now receive in the city. Eventually, too, we would like to see this program extend over to a cooperative training in nursing education. A very important aspect of the plan is the selection of the right man to act as coordinator in the individual hospitals. In two of our hospitals which did not appoint such coordinators, because the proper men were not found, the program did not go very well. We have not been conscious of some of the difficulties which Dr. Wilkinson mentioned. Our faculty has been enthusiastic about it and there has been no trouble in having senior faculty members go out to make these visits. In part that may be due to the fact that they all received an honorarium for each visit, but in all events they have done it with enthusiasm. The hospitals have not shown any feeling that the University was "moving in on them." Some of the attendants at the hospital found that under this new plan they had to devote more time to ward service in the hospitals and to intern residency training, and that irked a bit; they of course were the first to admit that was what they should be doing, and it was one of the good features of the plan, and now they do it. The cost is an important feature. We made perfectly clear to every hospital that came into this program with us that we could not carry it out of the University budget. When the funds which we now receive come to an end, either funds will have to be provided from some other sources or, by that time, it should be sufficiently interesting and important to the hospitals so they will take over the cost. I estimate that the program costs about \$3,000 to \$4,000 in each of these hospitals, depending on how much one pays as a stipend to the coordinator of the hospital and whether or not one included in it the lack of funds lost through the fact that we waive a tuition for the residents who come to the college during that part of their training. This figure of \$3,000 to \$4,000 does not include the overhead of operating the whole plan.

QUESTION: What is the smallest hospital in size desirable for such an affiliation? Do they have any trouble getting interns? Does this program help them get interns?

DR. WILKINSON: The size of the hospital varied with whether we were trying to train specialists or general practitioners. It was felt that a hospital of one hundred beds could offer enough to give a man for the six months that he is there but not enough to give a man proper training in the specialty field. In those hospitals they would average one hundred and fifty beds or larger. The hospitals have had some difficulty in getting interns, but a decreasing difficulty in getting interns each year. We have a joint certificate with the University of Michigan Medical School and affiliated hospital to the effect that such and such a hospital is affiliated with the University of Michigan, and both the dean of the school and the chief of the service at the local hospital sign the certificate to the amount of training they have had as interns and residents. The prospectus of the hospitals that goes out to medical schools usually includes a statement to the effect that they are affiliated with the University of Michigan and that a nine months' period of basic science continuation study is offered at the University of Michigan during the resident training period. The general practice interns apply directly to the University of Michigan, and the University of Michigan makes appointments there. In the specialty programs the local hospitals make the appointments.

Economics of the Hospital System

ELI GINZBERG, PH.D., New York: The New York State Hospital Survey and Planning Commission entered into a contract with Columbia University six months ago, to have a study made of the entire hospital facilities within the State of New York. The commission is responsible for the channeling of the Hill-Burton moneys, among its other duties, for the erection of new hospitals. The commission awakened to the fact that it would be dubious to try to build new hospitals unless one had a clear picture of the financial underpinnings and general strength of the existing hospital plan. It was to have a broad social-economic study undertaken that the commission went to Columbia and entered into this contract. We have

been under way about six months with this study, and a host of complicated problems come to the fore. I am going to consider those problems which bear more particularly on the interest of a group like this. I need some help.

I start with the presupposition that no matter how much or how little money is spent for hospital service or any other health activity, one ought to try to do two things; that is, to get the best that money can buy and the most that money can buy. The total expenditures for hospital care within the United States represent still a relatively small proportion of the total bill for medical care—something like \$2,000,000,000 out of an annual budget of over \$8,000,000,000. The hospital plan of the United States grew up in an era of free competition when individuals or groups decided to build hospitals. They built hospitals more or less without regard for or any detailed consideration of other hospital facilities near or far. As modern medicine has developed we have become more aware of the fact that one cannot really look at the adequacy of the isolated hospital, but ought to think in terms of a hospital system or an integration among a group of hospital units. If you do not do that, the likelihood is that on one hand you will run into duplication and wasteful facilities, and on the other hand to an imbalance of facilities. If you have too many, or the wrong proportion of facilities, you are going to run into serious waste.

Looking at a hospital from the outside, as an economist, it seems as if a good hospital has to have a larger amount of expensive equipment and highly specialized personnel. They need expensive laboratories, x-ray machines, apparatus, and so on. They need skilled personnel to make efficient use of the equipment. The full utilization of that expensive equipment and skilled personnel cannot be carried by the inpatients alone. You do not at any time have a sufficient number of inpatients who require the full utilization of all these overhead facilities. Since somebody (broadly, the community) is paying for those facilities, it seems unwarranted to have them utilized far below their reasonable load factor. This means that one ought to start thinking of how to make effective use of these overhead facilities for an increasing number of patients who are not in the hospital but who can be treated on an ambulatory basis either for diagnostic or for therapeutic purposes. There ought to be some way of building a bridge between the people on the outside and the existing facilities on the inside so that we can get these expensive facilities down in cost in order that more people can use them. The community cannot do everything it would like to do with respect to health; therefore I think it behooves all of us to figure out how it can at least make the most use of what it has.

When one encounters a shortage problem, perhaps the present planning in the utilization of skilled personnel is not at a maximum. I should like to raise the question whether it would be possible, protecting the basic doctor-patient relationship, still to work out more effective designs for the treatment of inpatients and also ambulatory patients who use a hospital facility, just because of the fact that the hospital makes it somewhat easier to go over to a team approach. In our calculations on the nursing picture, the committee arrived at an estimate that 70 per cent of the entire nursing functions of the country could be efficiently performed by nurses who had had only nine to twelve months of training, subject to the one proviso that about 30 per cent of them would be team leaders and really well trained professional nurses. In the Army experience, of which I can talk with some five years of background, we never could have met the obligations of the last war had we not trained some half-million medical technicians. We trained them within three to six months, and then had them learn much more on the job, with the consequence that one could get a tremendous additional volume of work load performed without pushing against the scarcest categories of personnel—the physicians and nurses—all the time. The hospital seems to be a logical area for intelligent experimentation with respect to new team approaches. So far I have found little experimentation outside of governmental hospitals, and not enough inside of them.

I believe we have become too hospital conscious in the country as a whole. That has been strengthened by virtue of the fact that Blue Cross, for all of its other advantages, is inpatient. I think that serious as it is not to have hospitals

where they are needed, it is equally preposterous to try ever to utilize them, because from an economic point of view the most expensive thing about hospital care is feeding patients and giving them service which ordinarily they get at home. The matter becomes of tremendous importance if one projects the present trends as to the needs for hospitalization for the chronic patients and for the neuropsychiatric patients. One of the New York psychiatrists said that if present trends continue, one will have only a choice between euthanasia and bankruptcy. It means that we must work out a series of approaches which will not lead to an absolutely indefinite expansion of more hospital beds, more patients in beds.

In summary, long overdue is the working out on a regional basis of a much more explicit form of integrating small outlying hospitals, intermediate hospitals and large teaching hospitals, and the insuring that areas are covered not necessarily by building hospitals everywhere, but by being sure that people can get hospital care and where they need it—and this includes moving a patient to the hospital as well as the hospital to the patient. Secondly, we ought to worry much more about the effective and full utilization of the expensive equipment and specialized personnel currently required by hospitals in order to handle the essential parts of hospital care for inpatients, and figure out how to spread that apparatus and that skilled personnel so that it can treat a much larger number of patients. Thirdly, I would like to see more experimentation with the general field of a team approach, as to how one can use less skilled and less expensively trained persons under the supervision of senior, well trained persons, so as to cut out fantastic requirements that we have just projected.

There is no point in worrying about economics unless one can insure certain minimum standards of quality and preferably expanding standards. I have been impressed with the gap between the point of view of the good medical teaching schools, with their tremendous emphasis on group practice, and what goes on outside, where the private practice of medicine is still heavily weighted in terms of individual practice. There has grown up a kind of compromise on the outside, in which the individual practitioner works by himself part of the time and if he has a hospital affiliation, works as a member of a team the rest of the time. That is probably a good compromise. There has been a too nonchalant attitude toward the fact that by concentrating on quality within the hospital there has been a serious neglect about the hospital's contribution to quality outside the hospital. It would be highly desirable to figure out how to do a better job than one has done in having the hospital serve as a continuing training ground for physicians in private practice. It seems to be desirable to have the medical profession, and in particular perhaps the medical schools, feel that there is this kind of responsibility that they have not only to train a few very good persons at the top, but that they have to figure out how they can make a continuing contribution to raising at least the minimum standards of hospital care in the community.

That problem becomes particularly acute if the medical profession does not take action, for this reason: The welfare commissioners, who are becoming important purchasers of hospital care, cannot understand why they should receive a bill from one hospital 100 and frequently 200 per cent higher than for the identical procedure at another hospital. If it is left to the welfare commissioners, they will apply the logic of the economic market and will conclude that the best care is the cheapest care. If you would like them to use a more meaningful set of criteria, then a set of practical criteria which can be applied administratively to all hospitals within the state or some subdivision thereof should be established.

Another point on the question of quality: I am disturbed, when looking at the analysis of the total medical budget, to see not only the relatively small amounts being devoted to research, but, more subtly, the present way in which atmosphere and incentives are working to deflect so many potentially good persons from research areas into the clinical fields. The medical schools must be somehow responsible not only for producing good clinicians, but for trying to work toward a shifting of the total incentive picture. Perhaps one of the ways to do it would be to broaden the area in which the medical schools operate, and, perhaps, on a part time affiliation basis with a

larger number of hospitals, work out some partial practice and partial research time. Good research means using most of a man's time; but in medicine, unlike some other fields, one must continue to deal with patients in order to do good research. I see the danger to be particularly acute because of the national interest in improving service all the time. In this matter of broadening the service to the patient of today we are apt to sacrifice the patient of tomorrow. Aggressive leadership is long overdue on the part of medical schools in figuring out how to better staff and get more persons into research.

The hospital is not making as much use of its natural allies in the community as it might. There is not nearly the integration of the hospital and the practicing physician in the community that there ought to be. The hospital seems to cut the patient off at one stage of his illness, treat him and throw him out again. If this doctor-patient relationship is as important as you all think it is, then I should think it becomes doubly important to get the hospital into a much more intimate relationship with the practitioner on the one hand and the health department on the other, so that you gain some strength through allies. Although there is a whole area of hospital direction which is the logical and sole province of the medical profession, there are other legitimately interested parties as far as hospital policies are concerned. There is simply the ordinary citizen who is the taxpayer. Secondly, there is Blue Cross and other prepayment schemes, that have acquired a large amount of converts with respect to certain aspects of hospital operations. Thirdly, there are the welfare and health commissioners of the respective communities who also are interested parties.

The hospital would become a more efficient total operation within the broad scheme of medical and health care if more attention were paid to working out the administrative and planning structure of the hospital. Here, the medical schools have a particular contribution to make; they ought to try to divert some persons with predilections for administration into the field of broad hospital planning and administration. Not all of our hospital administrators need be medical people, but at least the leadership ought to come from a man with a good medical education who also has some imagination about broad problems.

DISCUSSION

DR. A. C. BACHMEYER, Chicago: I find it difficult to discuss this address because many of the problems outlined have no ready answers. I can only offer opinions on the points enumerated. We have the beginning, at least, of a mechanism for assessing the community need for hospital service. The appraisal and planning mechanism suggested is the formation of local groups or committees representative of those that are interested in the problem—the medical profession, the various health agencies, the community at large—to study the entire situation. Dr. Ginzberg pointed out the need for coordinating hospitals. We have had several examples across the country, developed in recent years, which indicate that by such coordination better medical care can be provided for the public. I refer to the Bingham Associates in Maine; the Salem Hospital in Massachusetts having a somewhat similar organization; the County Regional Plan at Rochester, N. Y., and in Michigan, under the W. K. Kellogg Foundation, a different type of organization. The University of Colorado is developing another plan but along similar lines. There is a challenge here to American enterprise, to the voluntary system, to develop similar endeavors without such "outside" support. I believe it can be done, but it requires leadership at the local, at the district and at the state levels. The organization of regional coordination ought to be not only on the service and educational levels, but also on the policy and administrative levels. I understand that at the Salem Hospital the development brings members of the Boards of Trustees of these smaller hospitals to the meetings of the Board of Trustees of the Salem Hospital. There is similar coordination at the professional level among the medical staffs, and at the administrative level as well. Through such regional development we may develop, on a voluntary basis, a system of hospitals throughout the country. We have no system of hospitals at present; each hospital is an independent, isolated unit, each planning and developing without regard to other hospitals in the area or the general need of the community.

Where institutions have developed in this haphazard manner, there is bound to be wastage of resources. As medical science advances it becomes necessary to purchase expensive equipment, establish laboratories and utilize the services of skilled technical personnel. Duplication and wastage of resources have been avoided in many instances through the development of arrangements between the individual and the hospital whereby the service is centralized and concentrated at the institution. Local health and hospital councils probably can assist in this area. The point which Dr. Ginzberg made about the use of less skilled personnel is realistic. We need at least as many better educated professional nurses as we have at present, and perhaps more, but we need many more trained attendants or vocational nurses to render a large bulk of the services that patients require. We need a group of professional nurses who know why services are being rendered, why observations of a particular type are necessary for the physician's understanding and care of the patient, and we need a large number of persons who know how to help. They can do the job under supervision. Our nursing schools today do not teach their students how to supervise and how to work with these less skilled persons in the service. Dr. Ginzberg's report on the function of nursing points out that perhaps we will eliminate what we call the staff nurse (the diploma nurse) and have a more highly skilled person who is capable of supervising two, three or four of these practical nurses or nurse assistants. That problem is acute. Probably the suggestion is not acceptable to the nursing profession and to many hospitals that are carrying on what are called nursing schools. The control of the admission and discharge of patients from the hospital is in the hands of the medical profession, and I hope these conditions will prevail. The cooperation of the physicians with Blue Cross plans has been notable in a number of areas. The average stay of Blue Cross patients in hospitals is less than seven days in Chicago. That is a rather short stay, and it means that there is cooperation; it indicates not only that the physician hesitates to admit a patient merely for diagnostic procedures that can be carried on with the patient at home, in his office or in a clinic, but also that he gets the patient out of the hospital when the need for inbed care is no longer present.

It is true that medical schools are teaching young men in an atmosphere of group practice. If you agree that the quality of medical care is of the highest in our teaching hospitals, then group practice offers promise of improvement in general standards. The decline in the number of graduates who go into solo practice today is evidence of the fact that they appreciate the value of having consultants and associates about them; it is also one factor in the difficulties which we are encountering through the maldistribution of medical practitioners. Elevation of the quality of medical care in hospitals is entirely a problem for the medical staff. It is a question of self policing. Members of the profession know how difficult that is, how hazardous it is to find fault with a colleague who may have made a mistake, knowing full well that we may encounter the same situation later. The maintenance of a high quality of service requires frank, unbiased audit of professional work, an alert, active auditing committee, and a professional review committee on all medical staffs. Skilful, competent, diplomatic, frank and courageous pathologists and radiologists are key persons. At present we have no mechanisms that permit us to compare the quality of professional service in one hospital with that in another. The staff committee and the staff of a hospital, their conception of good quality care and the audit of the professional service are the only criteria available at present. With reference to research, we must recognize that basically there are two types. Fundamental research requires training of skilful personnel, space and money, and should be restricted to those institutions in which qualified personnel and funds are available. The cost should not be added to the patient's bill for service. The conduct of research in our medical schools, its inclusion in our curriculums in such a manner that the undergraduate student is at least exposed to it and has an opportunity to participate in investigative studies, is an essential part of the medical student's education. The second type of research might be designated applied research or clinical investigation. Such studies require careful planning and competence on the part of the investigator, but they are costly only in time and effort.

Thousands of medical records every year find their way into filing cases and never see the light of day again. These records contain great amounts of valuable information and should be subject to review and study in every hospital. These records, properly made, readily form the basis for much clinical study, and there should be much more of it carried on. The sharp lines between curative and preventive medicine are fast disappearing. The public health services in many areas are undertaking case finding activities. Our outpatient services should be far better developed. Through the outpatient department and the diagnostic clinic that can be established in all hospitals, much duplication of effort and expense can be eliminated and the services of hospitals and health departments can be better integrated. There seems to be little sense in having a hospital laboratory doing the same type of work as is being done downtown in a public health department laboratory. Better relations between governing boards, the administration of the hospital and the medical staff, of course, are essential. Active liaison committees between the staff and the board and the administration have been the best mechanism for developing proper relationships. These relationships must be properly established if our hospitals are to be conducted in the best interests of the patient.

DR. CARROLL B. ANDREWS, San Francisco: It may be well to consider some of the basic principles relating to over-all medical care originating from the standpoint of a physician in private practice. As Dr. Ginzberg's address pointed out a number of critical questions, I too find several questions arising in my mind. The inefficient use of equipment in doctors' offices and in hospitals is admitted. Nevertheless, I should like to point out that the great development in the United States was brought about by the inefficient use in relation to the time used, first, of the long rifle of the scout and pioneer. He needed it only for a few minutes but he needed it definitely in those few minutes to protect and provide for himself and the public. The farmer used his plow only a short time during the season but the plow, the scythe, the mowing machine and the reaper had their definite uses. So the country physician often needs an x-ray unit and other expensive laboratory equipment immediately after his history taking and physical examination. The lack of availability of these essential instruments may have a deterrent effect on the broad programs of cancer, tuberculosis, gastrointestinal disease and cardiac disease case finding, diagnosis and treatment. These and many others are problems that originate in the doctor's office, the first point of contact where segregation of cases is now accomplished. How efficiently is scientific research carried on in institutions of higher learning? The tremendous costs should not deter us from scientific investigation! We should not be too greatly concerned about the use of expensive equipment in the individual doctor's office. There are problems which arise in a small community through so-called group practice. These may be corrected in some measure by a loose integration by the physicians' practicing as a group, pooling equipment and a common building. This mode of practice may come about slowly through the use of the small hospitals that are being constructed in the rural areas. This is the type of practice being developed in my own community. The development on a voluntary basis of our own twenty-three bed hospital has proved to be an excellent practical research laboratory in the medicoeconomic problems which are facing physicians, provides a common ground for frequent casual contacts, consultations and staff meetings. Coincidentally there has been an increasing tendency to share office space and equipment.

DR. GINZBERG: Concerning Dr. Andrew's statement, I should like to say that my emphasis is not only on the economical use but on the effective use also. There is a range of conditions, of skills and of apparatus that fits together, and that is for the private practitioner, working on his own or in loose affiliation. There are also types of equipment which require types of skill and that is what I should like to emphasize. It is impossible to conceive of each individual doctor's having a requisite amount of that skill. It was my conception that it was the second group, the highly specialized resources, which ought to be utilized efficiently, because they are so expensive and because they require such a high level of skill.

FEBRUARY 7—AFTERNOON

DR. HERMAN G. WEISKOTTEN, Syracuse, N. Y., Presiding

Classification Policies of the Selective Service System

COLONEL RICHARD H. EANES, Medical Corps, United States Army: Congress in the Selective Service Act of 1948 placed the responsibility for classification of registrants on the local boards which are established throughout the local communities of the nation. Thus a registrant is classified by his neighbors who are duly appointed for that purpose. Their judgment and decision in classifying is final but, in keeping with our democratic principles, is subject to appeal.

A physician developing a private practice who is liable under the Act must present sufficient evidence to his local board that he is actually engaged in his profession, that he cannot be replaced because of a shortage of personnel with his qualifications or skill and that his removal would cause material loss. If a physician is really busy, it would seem that it would not be difficult to present such evidence to the local board. Interns and residents present a similar problem.

We are aware of the shortage of doctors in the armed forces, and we have informed the local boards that commissions are available for young men who have the professional qualifications and are physically fit. We have not advised the local board that these men should be commissioned before consideration is given to them for occupational classification. Such a thing is prohibited in the Act, but we do feel that the acceptance of a commission by one of these young doctors would be further evidence that he may present to his local board to show his intent to serve the nation in its need. When we are asked, we are advising both the hospitals and the physicians to that effect. We have further stated, unofficially, that in our opinion a hospital should not enter into a residency contract with a young doctor until he has rendered enough active military service to relieve himself of liability under the Selective Service Act.

Identifying those students who have been accepted, or are pursuing full time courses in the study of the healing arts, has presented no serious problem. A more complex portion of this problem is the identifying of undergraduate students who are to be given occupational classifications in order to insure an adequate supply of qualified material to the professional schools in the years to come. It would be difficult to estimate how many men are actually taking so-called premedical courses in undergraduate schools. The number is far greater than the number of men who can be admitted to professional schools each year. It is obvious that not all men pursuing a premedical course can be granted blanket occupational classification. I may assure you that when a program is put into effect it is reasonable to expect that it will result in a pool of baccalaureate graduates sufficiently large to afford medicine its choice in selecting the 6,000 odd students needed each year. In fact, the adoption of this program may relieve medicine of some of the more routine elimination of applicants who are without proper qualifications and will make unnecessary the provisional admittance of pre-professional students two and three years before the anticipated commencement of a full time course in medicine. It behooves the serious student of medicine and the medical educators to have the local boards of the Selective Service System fully informed concerning the occupation of medical student registrants. I urge those who are vitally interested in this problem to continue to follow Local Board Memorandum No. 7 as it pertains to your professional students; that you likewise file SSS Forms No. 103 for those men approaching the end of their preprofessional course who are being actually admitted to your 1949 classes, and that you plan, on or about July 15, to prepare SSS Forms No. 103 for all students then actually admitted to the professional classes commencing in 1949.

DISCUSSION

QUESTION: Would a boy 18 years of age, eligible for college, be given an opportunity to study medicine?

COLONEL EANES: He must register at his local board or at some local board immediately after he turns 18. He is not eligible for service until he becomes 19 years of age. Before any future inductions, I am confident that a broad student deferment policy will be adopted and that there will be certain things required of this young man, whether he is going to study medicine or anything else, if he is going to remain in college. He will consult his school at the time he becomes 19 and he will be required to do certain things. If he does those things successfully, the school will certify him to his local board and will request occupational deferment for him. If his nineteenth birthday catches him in the middle of the year and he receives an order for induction, he will present to the local board that he is a college student, and under the law his induction must be postponed. This will not be of much benefit to him unless he is certified by his college.

QUESTION: If a man meets his state requirements of internship, completing the same as of July 1, 1949, and he has aspirations for a residency in a specialty board, it is my understanding that on completion of his internship that man automatically reverts to 1-A.

COLONEL EANES: Local Board Memorandum No. 7 does not apply to any registrant who is a graduate in medicine. It applies only to those who are studying medicine. Any registrant, no matter who he is, may ask his local board for occupational deferment. The person referred to has been occupationally deferred while he is serving his internship. He has the right to ask his local board to continue his deferment until his twenty-sixth birthday while he does a residency. I stated that unofficially we are advising the hospitals that in our opinion, because of the great need in the military forces for doctors, they should not consider a new residency contract except with men who have satisfied their liability under the Selective Service Act. That does not mean that a local board cannot defer this man. The local board can defer him, and the only way we could stop the local board from deferring him would be to appeal and have either the appeal board or the Presidential Appeal Board disagree and reverse the local board. I do not believe that we will in any unaggravated case ever appeal such a classification from a local board; that is, from national headquarters. The registrant can ask for a continued deferment while he is doing a residency. We simply feel that he should not. If the local board gives it to him, it is his. The final decision is the local board's, subject to appeal.

DR. W. B. PARKER, St. Louis: I have been asked by several medical students to file Form 103 for them before they have a Selective Service number. Should I do this or wait until they have that number from the board?

COLONEL EANES: The number does not keep you from filing. My idea, which I think is consistent with the workings of the local board, is that it should arrive at the local board, if this man is just turning 19, at about the same time his questionnaire gets back to the local board. In other words, to try to get him his occupational classification before any other classification can be given. So time it with him that you get the Form 103 through national headquarters and through the state headquarters, to arrive at the local board at about the same time that the questionnaire arrives. The local board will continue classification of all men between the ages of 19 and 26.

A question has been asked me whether, if a man is under orders or is classified 1-A and arrives at his twenty-sixth birthday and has not yet been inducted, the order for induction or the classification 1-A extends beyond the twenty-sixth birthday. The answer is that he has no liability for service from the day he reaches his twenty-sixth birthday. The law does place on him the obligation of keeping his local board informed as to any change in status, change in address, marital status, and the like, but he has no liability for service and he may not be presented for induction.

DR. HARVEY B. STONE, Baltimore: As elaborate as the initial program for the deferment of premedical students seems to be, it is such a tremendous safeguard and such an advance over the condition that prevailed in the last war that it is a great reassurance to those interested in the continuing supply of medical students.

Program of the United States Public Health Service. for the Improvement of Teaching in Cancer

DR. SAMUEL C. HARVEY, New Haven, Conn.: Something over a year has gone by since the first grants were made to schools of medicine by the United States Public Health Service for improvement of the teaching of cancer. This action was the result of a conference organized by the National Advisory Cancer Council. How these funds were to be used was wisely left to each school concerned. I have the impression that the situation which gave rise to this effort to improve the teaching in "cancer" was referable to the methods of teaching in the schools of medicine rather than the objectives, which have in general been of the highest order. Inadequate diagnosis and treatment is not peculiar to the field of cancer, though it may, in many instances, be more obvious there. This should not be held an indictment against the profession as a whole, for adequate knowledge has been, and still is to a great degree, lacking. Also, the awareness of the increasing importance of the so-called chronic diseases, in which cancer may be included by reason of chronology if for no other, is a matter of relatively recent development. In spite of these handicaps, a considerable number of physicians have kept pace with the changing picture and do not rely on what they were taught in schools of medicine, but rather on a continuing self enlightenment by acquaintance with current literature and with practice according to the experience of others. Knowing the degree to which a physician has done this, one can make, off hand, a favorable prognosis as regards the quality of his work. A primary problem at the present and so far as one can see into the future is that of obtaining teaching personnel in the field of "cancer" who are informed about and participating in research and at the same time familiar with the natural history of neoplasia not only in the experimental animal but also in man.

Pediatrics in the Medical Curriculum and the Intern Year

DR. JOHN MCK. MITCHELL, Philadelphia: The Study of Child Health Services of the American Academy of Pediatrics in 1947 conducted a survey of pediatric education in medical schools and in the hospitals approved for residency training in that field by the Council on Medical Education and Hospitals of the American Medical Association and the American Board of Pediatrics. This paper presents an appraisal of the pediatric training provided during the undergraduate course and in the intern year in the above hospitals.

It is obvious that a brief recapitulation of a study of this sort will lay considerable emphasis on deficiencies which were discovered. Pediatric education has shown a vast improvement in quantity and quality since the time of the Third White House Conference on Child Health and Protection in 1930 and even since the survey of medical education in the United States conducted under the auspices of the American Medical Association between 1934 and 1939.

Those pediatric departments which fail to give adequate training in such important categories as care of newborn infants and contagious disease should take steps to rectify these deficiencies. In some instances the fault lies in the lack of available clinical material. In many cases the major defects could be overcome by administrative reorganization. In some schools there are an insufficient number of hours allotted to pediatrics. In others the hours are offered but are poorly distributed. In other schools there should be a careful review of the area of responsibility of different departments. This is especially necessary with regard to the proper integration of training in the care of the newborn infant between obstetrics and pediatrics.

Not infrequently increase in the size of the pediatric staff would be necessary before it could undertake an appreciable increase in the teaching load. In some instances this would necessitate more teachers on a full time or near full time basis, which would of course entail a larger budget. Many times, however, the necessary increase in staff could be obtained by proper cultivation of well trained local practicing pediatricians. In other cases it could be accomplished by stimulating recent graduates to practice in the community by offering teaching appointments. A strong resident staff can carry a major share

of small group instruction. With the present great demand for pediatric residency appointments, a number of hospitals could readily augment this group with great benefit to the undergraduate and intern teaching program.

Orphanages and other homes for the custodial care of children offer fertile soil for the milder contagious diseases and other epidemics. Through affiliation with such institutions both house staff and students can obtain valuable experience in this field, which is so often curtailed.

It should be the aim of medical education to produce physicians at graduation who have had a thorough preparation in the basic medical sciences and an opportunity to observe and participate in the application of this knowledge in the various fields of medical practice. These ends have been achieved in full measure by many medical schools. With proper support and planning, they can, in the near future, be attained by all.

DISCUSSION

DR. WILBURT C. DAVISON, Durham, N. C.: Dr. Mitchell's paper emphasizes that pediatricians should spend more time in training for general practice. After all, the majority of child care in this country is carried on by general practitioners. Pediatric departments should stress the training which the general practitioner should have, rather than to spend, as many pediatric departments do, most of their time in the training of pediatricians. That training of pediatricians should be merely a by-product. In North Carolina 3 per cent of our physicians are pediatricians, and yet the survey of the American Academy of Pediatrics showed that only 7 per cent of the children were taken care of by pediatricians.

It has been difficult, as Dr. Mitchell pointed out, to decide whether it is safer to allow a number of students in the nursery or let them go out and practice without knowing anything about care of newborn infants. That problem has been solved in many medical schools, including our own, by abolishing the nursery. Right after delivery the children are placed in the bassinet along side the mother's bed or in an open ward if there are three or four mothers; not only does it avoid nursery infections but it allows the pediatric or obstetric student to become thoroughly familiar with problems of the newborn infant, and, also, it enables the mother to learn something about the care of her child. European hospitals do not have nurseries. Dr. Hess, one of the oldest pediatricians I know, said that when he started practicing there were no nurseries in the country. In order to keep this relationship with care of the newborn infant before the house staff, whenever delivery is scheduled a pediatric intern is there, and if the mother is known to be an Rh-negative possibility we have agglutinin ready, and the blood bank team is ready for replacement transfusions. One point which Dr. Mitchell did not bring out is that there should be much closer correlation between pediatrics and psychiatry. This was an unintentional omission, because he knows that a knowledge of child behavior problems by faculty and students is of great help. Our students participate as interns, under supervision, for a three month period in their senior year. They take active part in nursing problems, dietetic problems, changing diapers, and they learn how to give bottles. To carry on this program, the pediatric time should be as late as possible in the senior year, preferably in a block of two or three months, because the later one can place it the more training the students will have had in medicine, surgery, psychiatry and so on, and it allows pediatrics to correlate this previous training. We have gone one step further. Through the cooperation of three excellent general practitioners in North Carolina, we arranged an elective by which students go with these men for one or two weeks. Invariably they come back with a far better training than they would have had in the corresponding time in a pediatric hospital. Another way in which we have improved pediatric training is by giving members staff appointments. One has pediatrics under biochemistry, another one pediatrics in allergy, with the idea of bringing together an integration of these various fields in the pediatric problem. Hospital training in pediatrics, as Dr. Mitchell pointed out, is defective. In the two years of a mixed or rotating internship, with a half-year each of pediatrics and obstetrics, the six weeks or less which graduates get in intern years is of little use. The residents in charge encourage the men to stay

on and become trained as specialists rather than go through this rotation. If the specialty boards would require a two year mixed service as a prerequisite for specialty training, we could get more men into general practice. I should like to speak of refresher training in pediatrics. Of the many refresher courses given throughout the country, perhaps one of the best was started in 1914 when half a dozen pediatricians who liked to spend the summer in the town of Saluda invited the general practitioners from the surrounding states to come to a small children's summer hospital there, and they took turns giving lectures. The real benefit that the general practitioners had was that they sat around for ten days and had a chance to talk and think pediatrics. Last summer about two hundred physicians from North and South Carolina, Tennessee and Georgia came up there. As a result of that program there is a far higher standard of pediatric care among general practitioners in that area than there is in many other parts of the United States.

DR. CHARLES F. MCKHANN, Cleveland: That 75 per cent of medical care in children in this country is rendered by men who have had only inadequate training in medical schools, and who have acquired further information by brief internships, presents a serious problem. Three possible solutions arise. One is to improve the undergraduate training in this field. It seems to me more feasible to do this than to attempt to control the quality of the internships. Filling internships, however, soon is going to present a serious problem to hospitals, and if twice as many places exist as there are candidates to fill those places the students who have come to their deans must be advised to select the better places. This means that the poorer places must improve their services or do without interns. This already is happening, not only in internships but in residencies, and I think it will soon happen in the field of pediatric residencies. The better pediatric institutions, at present closed to interns, should make some arrangements to have intern training. The point that Dr. Davison made, that most of the men who come into an accredited pediatric service as part of a rotation stay on to become pediatricians, is a real problem. We try to save two places each year on our service for men who are aiming toward general practice. This is not many, about six men a year having training, because we have these men for four months each. The problem comes at the end of their year of rotation, to keep them from becoming specialists.

The other situation is the establishment of a satellite hospital system. As a member of the American Board of Pediatrics I look at it from this angle. Sending men out from accredited services to satellite hospitals for any considerable period results in a dilution of the service in the accredited hospital. In my opinion it is better to bring the men from the satellite hospitals to rotate through the center. Lastly, everybody underestimates the impact of medical investigation in the field of pediatrics. The two largest groups of causes of deaths in infants and children are being brought rapidly under control; namely, gastrointestinal disease and pulmonary disease. In 1935 and 1936 the hospital I was associated with admitted 600 children with pneumococcus pneumonia. Today we do not admit enough of these patients to show 1 case to students. Scarlet fever is rapidly getting into the same situation. Every hospital should have an isolation setup so that it can handle the types of patients who will remain from this rapidly disappearing group of communicable diseases. Although pediatricians or general practitioners have had this rather short service in the field, they can do things more effectively than could a pediatrician, regardless of how adequate or how thorough was his training, ten or twelve years ago. Our school is one of those that do not have any of these lacks that Dr. Mitchell spoke about. We had one at the time the survey was made, but it has since been remedied. We are one of the schools which give among the largest number of hours to the training of students in pediatrics. If the next ten years shows as much progress in the prevention and treatment of disease in children as have the last ten years, perhaps we will give up about a third of our time rather than seek more training for our medical students in pediatrics.

Psychiatry in Undergraduate Medical Education

DR. WILLIAM MALAMUD, Boston: This paper was published in THE JOURNAL, May 7, page 1.

DISCUSSION OF DR. MALAMUD'S PAPER

DR. WILLIAM S. MIDDLETON, Madison, Wis.: If we followed carefully the thesis as given to us, it is apparent that Dr. Malamud has put his finger on a sensitive point in regard to the preparation of the student for medicine. With the pressure of the sciences of chemistry, biology and physics, not only have the humanities been 'blotted out, but with a changing social complexion we have likewise given no heed to sociology, to economics or psychology. If we are to read the lesson from this text, it is well that we should go back to the sources and attempt to remedy these deficiencies. In the development of this topic, there is a strong emphasis on sequence through the four years of medicine. The strongest, I think, is the development of the interview technic. If, in the second year of medicine, in the course of history taking, the student is advanced one step further to the interview method of psychiatry history, we will have indeed contributed to his clinical development. Turning to the opposite side of the picture, if I admit as a clinician that 85 per cent of all patients who come to see me have some psychologic problem, I will grant there is need for great stress in this area of medical education. Furthermore, the general practitioner will take care of 85 per cent of these 85 per cent of human ills with psychologic problems. I would challenge Dr. Malamud's statement that the general practitioner would merely lance an abscess or amputate a part without having in mind the family that he is treating, the individual psychology, the economic impact of that particular event. Eventually he will integrate into his total picture a true psychologic approach to the patient's problem. In other words, in the general practitioner, the family counselor of today, we have integrated by experience rather than by exact discipline such a manner of approach as he would have for the product of his particular system. In medical education we are interested in evolving technics, methods, disciplines. Principles alone can last, and to this particular program we must give due weight concerning the principles which are involved. One may take the several years and the steps and stages that have been evolved by Dr. Malamud and apply them in the concrete example of the student's time. However, we must settle once and for all what we expect to turn out at the other end of the mill. I would question whether we would expect to turn out a man who was even incompletely trained in the psychoses. Too much of the error of psychiatric training in the past has resided in this jargon, in this mystic realm of psychiatric nomenclature. I believe there is definite movement away from that in the thinking of such a program as Dr. Malamud outlined, but we must be ever mindful that the theme is the rediscovered man as a whole. I have been teaching for thirty-six years and I thought I had always taught man as a whole. Last year, in San Francisco, one of my old students, Carl Menninger, rediscovered "man as a whole." They are simply playing with words. As general practitioners, as internists, through all of this past generation we have been dealing with the person as a whole; we have not lost sight of the impact of society on his problems, but in the newer concept of psychiatry, coming in by a circuitous path, we have a better approach in a finer discipline. I would not belittle the program that has been outlined, because it promises to the medical student a distinctly improved discipline of approach. However, I have a suggestion that perhaps of necessity we have used as an expedient at Wisconsin. Our first year students are taught medical psychology; in the second year they are taught psychologic pathology, and then, in addition to their routine exposure in psychiatry in the third and fourth year in medicine, and eventually in the several other subjects, we hope to have persons especially trained in psychiatry who are primarily internists, surgeons, obstetricians, and so on. In this fine outline of a program for psychiatric training of undergraduate medical students Dr. Malamud has sounded the advance. I believe it is a substantial improvement over anything we have generally throughout the country, and is distinctly better than that which we have in Wisconsin.

DR. W. B. HENDERSON, Oelwein, Ia.: I should like to reemphasize the importance of psychiatry and pediatrics. I make a practice of addressing every prospective mother by her first name. Certainly no one knows the patient better or more intimately than the obstetrician. I wonder whether or

not the original method of teaching the medical student by having him accompany the practitioner is not a good idea. Why cannot the sophomore and junior medical student during the summer come to the smaller communities and be in the hospital there? If there is a way that these smaller hospitals could be utilized in teaching the medical student it would be ideal.

DR. MALAMUD: I tried to stress in my paper that what we want to give these students is exactly what the general practitioner has developed by bitter experience after he has graduated from medical school. Certainly they were the ones who taught us psychiatrists what this type of psychiatry that I tried to present in my paper should be like. I did not stress giving students a great deal on psychoses or some of the intriguing morsels about psychoneuroses, but what I wanted them to learn is exactly what the general practitioner has learned during years of practice. It has been systematized by experimental work which has been done during the last twenty-five years. I agree with Dr. Middleton, that in the third and fourth year an attempt should be made to use as much as possible the internist, the surgeon and the pediatrician in teaching psychiatry to the medical students. For the time being we have to do it, but the time will come when enough of the surgeons, internists and pediatricians will have learned psychiatry from us psychiatrists, and then we will be able to teach psychiatry in a proper manner.

FEDERATION OF STATE MEDICAL BOARDS
OF THE UNITED STATES

FEBRUARY 7—EVENING

Observations of Medical Conditions in Europe

DR. R. L. SENSENICH, South Bend, Ind.: The medical situation in Europe has deteriorated tremendously. In Germany, even before the recent war, conditions had deteriorated. Part of this was a result of Hitler's preparation for war and the fact that young men were admitted to medical school without the training which had been required in preparation for the medical course. At present there are a sizeable number of physicians in Germany fully licensed to practice, whose preparation is not equal to a high school education and whose medical training was equally deficient. They were licensed to provide a larger number of physicians to be in readiness for the war. These men are a problem at this time. Men are not selected for medicine. There is no examination on admission. Anyone who desires to be a physician must be admitted to school provided there is an opening and an opportunity for that training. At the end of the second year an examination is given. The student then finishes the rest of his training and at its conclusion is privileged to practice without examination. I had an opportunity to talk to the doctors in each of the medical centers.

A person is licensed to practice in a given community. This *Niederlassung* is unfortunately tintured by political controls. Without examination of any kind the person applies and is given permission to practice in a particular location.

Two agencies have to do with the conduct of professional activity. One is the *Arzte Kammer*. It is not scientific; it is a union of the profession to protect itself against government encroachment. Then there is the regional licensing board, and between the two is the governmental agency from which physicians receive their pay for the things which are done under the *Krankenkasse*. This is true also in Austria.

The individual is dependent for about 60 per cent of his income on insurance. At the conclusion of a service he bills this intermediate organization, and they in turn collect from the government to pay him.

The representatives of the many nations in the World Medical Association were agreed on certain principles. and they were enthusiastic about the principles with the exception of two, one of which was that any social security or insurance plan must be open to the participation of any licensed physician. This they felt would destroy them. To that the suggestion was made, Why do you not cancel out all existing licenses, and begin over by examining each individual, not by an extensive medical

of small group instruction. With the present great demand for pediatric residency appointments, a number of hospitals could readily augment this group with great benefit to the undergraduate and intern teaching program.

Orphanages and other homes for the custodial care of children offer fertile soil for the milder contagious diseases and other epidemics. Through affiliation with such institutions both house staff and students can obtain valuable experience in this field, which is so often curtailed.

It should be the aim of medical education to produce physicians at graduation who have had a thorough preparation in the basic medical sciences and an opportunity to observe and participate in the application of this knowledge in the various fields of medical practice. These ends have been achieved in full measure by many medical schools. With proper support and planning, they can, in the near future, be attained by all.

DISCUSSION

DR. WILBURT C. DAVISON, Durham, N. C.: Dr. Mitchell's paper emphasizes that pediatricians should spend more time in training for general practice. After all, the majority of child care in this country is carried on by general practitioners. Pediatric departments should stress the training which the general practitioner should have, rather than to spend, as many pediatric departments do, most of their time in the training of pediatricians. That training of pediatricians should be merely a by-product. Eventually he will integrate into his total picture a true psychologic approach to the patient's problem. In other words, in the general practitioner, the family counselor of today, we have integrated by experience rather than by exact discipline such a manner of approach as he would have for the product of his particular system. In medical education we are interested in evolving technics, methods, disciplines. Principles alone can last, and to this particular program we must give due weight concerning the principles which are involved. One may take the several years and the steps and stages that have been evolved by Dr. Malamud and apply them in the concrete example of the student's time. However, we must settle once and for all what we expect to turn out at the other end of the mill. I would question whether we would expect to turn out a man who was even incompletely trained in the psychoses. Too much of the error of psychiatric training in the past has resided in this jargon, in this mystic realm of psychiatric nomenclature. I believe there is definite movement away from that in the thinking of such a program as Dr. Malamud outlined, but we must be ever mindful that the theme is the rediscovered man as a whole. I have been teaching for thirty-six years and I thought I had always taught man as a whole. Last year, in San Francisco, one of my old students, Carl Menninger, rediscovered "man as a whole." They are simply playing with words. As general practitioners, as internists, through all of this past generation we have been dealing with the person as a whole; we have not lost sight of the impact of society on his problems, but in the newer concept of psychiatry, coming in by a circuitous path, we have a better approach in a finer discipline. I would not belittle the program that has been outlined, because it promises to the medical student a distinctly improved discipline of approach. However, I have a suggestion that perhaps of necessity we have used as an expedient at Wisconsin. Our first year students are taught medical psychology; in the second year they are taught psychologic pathology, and then, in addition to their routine exposure in psychiatry in the third and fourth year in medicine, and eventually in the several other subjects, we hope to have persons especially trained in psychiatry who are primarily internists, surgeons, obstetricians, and so on. In this fine outline of a program for psychiatric training of undergraduate medical students Dr. Malamud has sounded the advance. I believe it is a substantial improvement over anything we have generally throughout the country, and is distinctly better than that which we have in Wisconsin.

DR. W. B. HENDERSON, Oelwein, Ia.: I should like to reemphasize the importance of psychiatry and pediatrics. I make a practice of addressing every prospective mother by her first name. Certainly no one knows the patient better or more intimately than the obstetrician. I wonder whether or

not the original method of teaching the medical student by having him accompany the practitioner is not a good idea. Why cannot the sophomore and junior medical student during the summer come to the smaller communities and be in the hospital there? If there is a way that these smaller hospitals could be utilized in teaching the medical student it would be ideal.

DR. MALAMUD: I tried to stress in my paper that what we want to give these students is exactly what the general practitioner has developed by bitter experience after he has graduated from medical school. Certainly they were the ones who taught us psychiatrists what this type of psychiatry that I tried to present in my paper should be like. I did not stress giving students a great deal on psychoses or some of the intriguing morsels about psychoneuroses, but what I wanted them to learn is exactly what the general practitioner has learned during years of practice. It has been systematized by experimental work which has been done during the last twenty-five years. I agree with Dr. Middleton, that in the third and fourth year an attempt should be made to use as much as possible the internist, the surgeon and the pediatrician in teaching psychiatry to the medical students. For the time being we have to do it, but the time will come when enough of the surgeons, internists and pediatricians will have learned psychiatry from us psychiatrists, and then we will be able to teach psychiatry in a proper manner.

FEDERATION OF STATE MEDICAL BOARDS
OF THE UNITED STATES

FEBRUARY 7—EVENING

Observations of Medical Conditions in Europe

DR. R. L. SENSENICH, South Bend, Ind.: The medical situation in Europe has deteriorated tremendously. In Germany, even before the recent war, conditions had deteriorated. Part of this was a result of Hitler's preparation for war and the fact that young men were admitted to medical school without the training which had been required in preparation for the medical course. At present there are a sizeable number of physicians in Germany fully licensed to practice, whose preparation is not equal to a high school education and whose medical training was equally deficient. They were licensed to provide a larger number of physicians to be in readiness for the war. These men are a problem at this time. Men are not selected for medicine. There is no examination on admission. Anyone who desires to be a physician must be admitted to school provided there is an opening and an opportunity for that training. At the end of the second year an examination is given. The student then finishes the rest of his training and at its conclusion is privileged to practice without examination. I had an opportunity to talk to the doctors in each of the medical centers.

A person is licensed to practice in a given community. This *Niederlassung* is unfortunately tintured by political controls. Without examination of any kind the person applies and is given permission to practice in a particular location.

Two agencies have to do with the conduct of professional activity. One is the *Arzte Kammer*. It is not scientific; it is a union of the profession to protect itself against government encroachment. Then there is the regional licensing board, and between the two is the governmental agency from which physicians receive their pay for the things which are done under the *Krankenkasse*. This is true also in Austria.

The individual is dependent for about 60 per cent of his income on insurance. At the conclusion of a service he bills this intermediate organization, and they in turn collect from the government to pay him.

The representatives of the many nations in the World Medical Association were agreed on certain principles, and they were enthusiastic about the principles with the exception of two, one of which was that any social security or insurance plan must be open to the participation of any licensed physician. This they felt would destroy them. To that the suggestion was made, Why do you not cancel out all existing licenses, and begin over by examining each individual, not by an extensive medical

examination but by an investigation of their training background and experience, and then determine that the men of experience and training should be licensed, and require that those not sufficiently trained do additional training so they will be qualified and maintain medical standards?

There are constantly entering into the British and the American zones men who escape from the Russian area who have had proper training and experience and who are as well qualified to practice as are those there now but who, permitted to practice, will increase the number of physicians so greatly under the Niederlassung that they say, "We can't possibly have that." That is the situation confronting them on a licensure basis.

At that time the individual physicians were receiving about eight reichmarks per month per individual on the panel and they were permitted to have 1,500. As the physician was required to take care of the dependents of those family heads, he had a sizeable number who had to be taken care of within the yield of this panel. We found that the best physicians, under ordinary circumstances, had about \$300 to \$400 a month for a three month period with which to take care of all these families and their dependents. They received the equivalent of about 40 cents per house call. For obstetrics they received 30 marks, or about \$3; for an appendectomy 30 marks; for setting a fracture 30 marks; for an extensive chest operation 50 to 60 marks; in addition to this, the surgeon might accept from a patient 100 marks at 10 cents per mark, or an equivalent of \$10, purely as a voluntary offering on the part of the patient.

What can be done for these people? We informed them we were not there to encourage or to press for any changes in their local governments as they wished them. We were there to encourage them to come to higher levels and to bring medicine above the political structure and above the economic distress in which it presently is found, and to try to get them to think of the best possible medical service, and then to try to establish that kind of program which would make it possible of attainment. We met with the outstanding doctors in the area and were much encouraged to find them beginning to think a little above their present distress level.

FEBRUARY 8—MORNING

DR. EARLE G. JOHNSON, Grand Island, Neb., Presiding

Address of the President

DR. EARLE G. JOHNSON, Grand Island, Neb.—Dr. Johnson pointed out that the medical examining boards comprise the only group that safeguard the respective states in the licensing of properly qualified applicants to practice the healing art. He suggested an American Board of Preventive Medicine and Public Health equal in rank to the other American boards as the qualification essential to those laboring in this field of medicine. He recommended the enactment of a resolution by the federation against state or socialized medicine; also that the federation take action to support a step to make more attractive to young physicians the military services of the United States and to encourage volunteers for such service in greater numbers. Dr. Johnson discussed the plight of the displaced physicians who have recently come to this country from abroad, pointing out that many of them are older graduates of foreign schools at a time when training in those schools compared favorably with our own of the same date; he advised a further study of this problem and some immediate recommendations for alleviation of it. He pointed out that all of the basic science boards except those of Florida, Michigan, South Dakota and Washington have discretionary power to issue a certificate in the basic sciences without an examination to those presenting satisfactory evidence of having passed an examination in the basic sciences before a board authorized to issue licenses to practice in any state or territory of the United States, and that if such discretionary power could prevail it would facilitate the interchange of physicians from one state to another and relieve much of the delay and conflict in medical licensure that now exists. Dr. Johnson also recommended that the federation support the efforts of the American Medical Association and other organizations to complete a worldwide evaluation and classification of medical colleges.

Medical Education in Denmark, Norway and Sweden

DR. ALBERT B. SABIN, Cincinnati: In 1947 I went to Denmark to attend the International Microbiological Congress and attempted to obtain information pertaining to medical education.

Denmark, with a population of 4,000,000, has one medical school in Copenhagen and a partial school in Aarhus in which students can obtain most of their preclinical subjects and part of their clinical studies but must go to Copenhagen to complete their studies. In 1944 the total number of physicians licensed in Denmark was 165. The average age of students on admission is eighteen years. Duration of university studies is seven to eight years, and after the completion of these studies there is a compulsory internship of one year before a physician can be licensed for full practice. In Sweden, with a population of 6,800,000, there are three medical schools and an additional school is projected in Gothenburg. The duration of university studies is eight to nine years, which includes about one year's work which would correspond to one year's rotating internship, and the internship is thus included in the university studies. Norway, with about 3,100,000 population, has only one medical school, at Oslo, but there is one projected at Bergen. The university studies are shorter than in any of the other Scandinavian countries, six to seven years, and no internship is required.

In Denmark, the premedical part of the study is only one year, in Sweden only half a year and in Norway only one year. Their preclinical studies extend over a period of three years in Denmark, two and a half years in Sweden and two years in Norway. The strictly clinical years are three years in Denmark, which does not include the internship, five years in Sweden, which does not include the internship, and three years in Norway, where there is no internship.

In the clinical years, whereas American medical students spend two years, students in Denmark spend three years, students in Sweden spend four years and students in Norway spend three years covering the same subjects. These studies include for the most part practical work not only on the wards in medicine and surgery but all the specialties as well. Most of the teaching is bedside, and there are many lectures during this period, especially in Denmark, where education is regarded as free. A student can attend the lectures or not as he pleases. The same thing would appear to be true in the other countries.

The teaching is done in hospitals which, at least in one instance, are predominately under university control. In Denmark there is the Riggs Hospital, which has been in existence since 1910 and some of which is now outmoded, which constitutes the chief hospital for clinical teaching. However, they have a number of so-called extraordinary professorships, in which the chiefs of service in various other hospitals also have small groups of students who are taught particularly in the specialties. In Sweden, the hospitals are not only those of the Karl Institute, which is perhaps one of the finest teaching hospitals in the world, also new hospitals which the city of Stockholm has built and which compare favorably with some of the finest hospitals in the United States. The hospitals in Upsala also are of the highest order.

Regarding licensure, in Denmark when they finish the university studies they obtain a limited certificate. They receive the degree with which a person can assist the physician, can serve an internship, can substitute for a short time but cannot practice medicine. After he has spent an additional year, of which at least one month must be in obstetrics and the remainder in medicine and surgery, he can get a full certificate which permits him to practice medicine, but most doctors at that time feel the necessity of continuing further studies. There are no examinations by the state. When the hospital says that he has finished satisfactorily and when the university says that he has finished his studies satisfactorily, the National Health Service gives him his certificate. In Sweden, the university degree received by the student at the end of eight and one-half to nine years is licentiate in medicine, and this automatically confers on him a license. There are no further examinations. In Norway persons graduated from the university can practice immediately.

The M.D. degree is a special requirement which takes two to three years of additional studies and requires a thesis. It,

actually costs a student almost \$1,000 to \$2,000 to publish his thesis.

In Denmark it takes five years of special study before one can be recommended by the Board of Specialists. In Sweden it requires three to five years. In Denmark the first two years must be spent in subjects in which the student will not ultimately specialize and the last three years are spent in his specific field. When the Board of Specialists certifies a person the National Health Service automatically approves him. These countries are aware of the importance of refresher courses for general practitioners.

About one fourth of the medical students are women. The number of scholarships and donations is hopelessly inadequate, considering the number of worthy applicants, and the question of some form of student salary furnished by the state has been raised in some quarters. The students' timetable is full, so there is little chance of earning money and little opportunity to take part in general life.

Medical education in the Scandinavian countries is superior to that in any other country. However, it may look to the United States for certain aspects of education because of the possibilities for improvement. Is it wise to raise every doctor as if he were going to be a medical researcher rather than a general practitioner?

Medical Education in Poland and Finland

DR. EUGENE B. FERRIS JR., Cincinnati: The purpose of my trip to Poland and Finland was a teaching mission organized by the Unitarian Service Committee and the World Health Organization. It consisted of seven other American physicians and surgeons, in some phases of the trip, from Czechoslovakia, Switzerland, England and Sweden. We had an opportunity to live fairly close with these physicians and thereby get information about the situation in those countries.

We spent six weeks in Poland, where we were allowed freedom to see and do what we pleased. Poland, which is at the border of Eastern and Western culture, has been a battleground between the East and the West for centuries. Before the last war it was essentially a feudal state. Medicine was almost completely morphologic and aristocratic in its orientation. With the occupation of the Germans there was begun a systematic program of extermination, and some 4,000,000 Jewish Poles and a larger number of non-Jewish Poles were exterminated. The basic philosophy of the Germans was that the Jews and the Poles were inferior races, meant only for labor. Of 13,000 physicians, only 7,000 remained after the war; 2,500 of 3,700 dentists lost their lives, and 2,000 of 5,500 pharmacists. Partially or completely destroyed were 400 of 667 hospitals, 7 out of 9 nursing schools, 4 out of 5 schools for midwives, 29 out of 45 tuberculosis sanatoriums, and 24 out of 25 spas. Nearly all laboratory and x-ray equipment was moved out of the country. Public health suffered as a result. In a partial survey of Warsaw just after the war some 25 per cent of the people given roentgen examinations had open tuberculosis. Syphilis and gonorrhea were rampant, and typhus took some 100,000 persons in the Jewish Ghetto alone over a period of two and a half years during the occupation.

Poland is thus faced with the problem of training 7,000 physicians in addition to the usual quota of about 600 per year. The schools are greatly understaffed, but the professors and those teachers available are of high caliber. In July 1948 the medical faculties at five university centers had already been reconstituted and three medical academies were organized in areas outside university centers, giving them eight completed staffed medical schools. A great deal of teaching is of the didactic type, but this is compensated for somewhat by the fact that after five years of medical school each student must complete two additional years of supervised medical practice in hospitals or rural health centers before being licensed to practice.

The entire medical curriculum has been revised recently to meet present needs. Before the war each department was independent of other departments in teaching and practice methods. The deanship was rotated biyearly among the professors. The new organization calls for a full time dean with definite authority to coordinate and integrate the teaching.

Applicants to medical schools must meet certain basic intellectual requirements, but beyond this about 50 to 60 per cent must come specifically from various segments of society, such as the peasant group, the laboring group, government workers and professional men. About 50 per cent of the present students are women. In the new program less time is given to anatomy and more to the social sciences and to the social and preventive aspects of medicine. Medicine is almost entirely controlled by the government; yet a considerable amount of private practice still takes place. Salaries are so low that teachers and physicians must supplement them by either practicing on the side or holding two jobs.

The hospitals are operated by the Ministry of Health and the medical schools by the Ministry of Education. Thus the teaching hospitals are assigned twice the number of medical personnel as are the nonteaching hospitals, half being paid by the Ministry of Health and half by the Ministry of Education. Likewise, the Ministry of Education pays for and assigns to the preclinical departments and premedical departments the same relative amount of teaching personnel as it does to the clinical departments. This in effect will tend to strengthen the preclinical departments in the future.

At the moment public health and preventive and the social aspects of medicine seem to take precedence over individual patient attention. Already typhus and typhoid are under control. Both syphilis and gonorrhea have been brought under control by mass methods of case finding and chemotherapy. The sanatoriums are being rebuilt and constructed at a rapid pace. All newborn children are being given routine vaccinations with BCG, and a program of mass case finding by roentgen ray is well under way.

One came away from Poland thinking less about the medical curriculum and more about the superb spirit of the Polish people and the drive with which Polish medicine is rehabilitating itself despite the blows of the past and a subtle but all-pervading fear and uncertainty of what the future may bring.

Finnish medicine contrasted in many ways with what we experienced in Poland. The Finns within two and a half years practically assimilated some 300,000 Karelians, representing one tenth of the entire population, who moved over to Finland when Russia annexed the Karelian Isthmus.

The majority of the medical staff spoke English and had a general outlook not unlike our own. Until the end of the war there was only one medical school at the University of Helsinki which turned out eighty medical graduates per year. They plan to graduate an additional forty students per year for the next ten years and have already created another medical school at Turku, which will concentrate on the last three years of the five year course. The premedical curriculum is essentially the same as that of the other Scandinavian countries. Medicine in Finland is influenced at present by Scandinavian medicine.

The University of Helsinki is an excellent medical school with facilities which excel those existing in a number of American medical schools. Facilities for clinical teaching are unsurpassed. Like many European schools, the various departments tend to be isolated from one another and the curriculum suffers from an excess of didactic lectures and inadequate tutorial supervision. Although a great deal of clinical research is going on, it is in the main of the descriptive type with little basic or physiologic oriented research. Teaching is directed primarily to the training of general physicians. Specialization is not so highly developed. However, the Finnish graduates are doing an excellent job of medical practice and a great deal of this success is due to the healthy attitude of the physician to the patient as a human being. This attitude is reflected not only in medical teaching and practice but in the architectural and functional planning of the hospitals and in their administration.

Licensing of Foreign Medical Graduates in the United States

DR. CREIGHTON BARKER, New Haven, Conn.: This paper was published in *THE JOURNAL*, May 7, page 10.

The British National Health Act

DR. MORRIS FISHBEIN, Chicago: This paper was published in *THE JOURNAL*, March 5, page 639.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II*. Various Centers. June 20-22, Sept. 12-14. *Part III*. June, various centers. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY, INC. *Written*. Various Centers. July 15. *Oral*. Oct. 16-20. Sec., Dr. Curtiss B. Hickcox, 745 Fifth Ave., New York 27.

AMERICAN BOARD OF INTERNAL MEDICINE: *Oral*. Philadelphia, June 1-3. *Written*. Oct. 17. Asst. Sec.-Treas. Dr. W. A. Werrell, 1 Main St., Madison 3, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: *Oral*. Chicago, June 1949. Sec., Dr. W. J. German, 310 Cedar Street, New Haven, Conn.

AMERICAN BOARD OF OPHTHALMOLOGY: *Oral*. New York, June 11-15; St. Louis, Oct. 15-19; Boston, December. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY. *Part II*, New York City, Jan. 1950. Final date for filing application for Part II is Aug. 15. Address: Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14, Calif.

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

AMERICAN BOARD OF PEDIATRICS: *Written*. Under local monitors, June 24. *Oral*. Cleveland, Sept. 16-18; New York City, Oct. 21-23; Chicago, Dec. 9-11. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

AMERICAN BOARD OF PHYSICAL MEDICINE. Philadelphia, June 4-5. Sec., Dr. R. L. Bennett, 30 N. Michigan Blvd., Chicago.

AMERICAN BOARD OF PLASTIC SURGERY: Examinations are given in June and November of each year in the home town of applicants. Sec. Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY, INC. *Special Examination*, October. Place to be announced. Final date for filing application is July 15. December, New York City. Sec. Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF RADIOLOGY. Atlantic City, June 2-4. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF SURGERY: *Written*. Various Centers, October 26. Final date for filing application is July 1. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

AMERICAN BOARD OF UROLOGY: *Written*, December. *Oral and Clinical*. Chicago, Feb. 11-15. Final date for receipt of case histories is Sept. 1, 1949. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18, Minn.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: *Examination*. Montgomery, June 28-30. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

ARKANSAS: * *Little Rock*, June 9-10. Sec., Dr. L. J. Kosminsky, Texarkana. *Eclectic*. Little Rock, June 9-10. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Examination*. San Francisco, June 21-23. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento.

COLORADO: * *Examination*. Denver, June 20-22. Sec., Dr. W. W. King, 831 Republic Bldg., Denver.

CONNECTICUT: * *Examination*. Hartford, July 1. Secretary to the Board, Dr. Creighton Barker, 258 Church Street, New Haven.

DELAWARE: Dover, July 12-14. Sec., Dr. J. S. McDaniel, 229 South State St., Dover.

FLORIDA: * *Examination*, Jacksonville, June 26-28. Sec., Dr. Frank D. Gray, 12 N. Rosalind Ave., Orlando.

GEORGIA: *Examination*. June 8-9, Atlanta and Augusta. *Reciprocity*. Atlanta, June. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

GUAM: *Endorsement*. Agana, Last Friday of each month. Sec., Capt. C. K. Youngkin, Dept. of Public Health, Guam. % F.P.O., San Francisco, Calif.

HAWAII: * *Examination*. Honolulu, July 11-14. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu.

IDAHO: Boise, July 11-13. Sec., Miss Estella S. Mulliner, Bureau of Occupational Licenses, 355 State House, Boise.

ILLINOIS: Chicago, June 28-30. Superintendent of Registration, Mr. Fred W. Ruegg, Capitol Building, Springfield.

INDIANA: *Examination*. Indianapolis, June 21-23. Sec. Board of Medical Registration and Examination. Dr. Paul R. Tindall, 416 K. of P. Bldg., Indianapolis.

IOWA: * *Examination*. Iowa City, June 13-15. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

KANSAS: Kansas City, June 1-2. Sec., J. F. Hassig, 905 North 7th St., Kansas City, Kans.

KENTUCKY: *Examination*. Louisville, June 15-17. Sec., Dr. Bruce Underwood, 620 S. 3rd St., Louisville 2.

LOUISIANA: New Orleans, June 6-8. Sec., Dr. Roy B. Harrison, 1507 Hibernia Bank Bldg., New Orleans.

MAINE: Augusta, July 5-6. Sec., Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: *Examination*. Baltimore, June 21-24. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore. *Homeopathic*. Baltimore, June 14-15. Sec., Dr. John A. Evans, 612 West 40th St., Baltimore.

MASSACHUSETTS: *Written*. Boston, July 12-15. Sec., Dr. George L. Schadt, 413 E. State House, Boston.

MICHIGAN: * *Written*. Detroit and Ann Arbor, June 13-15. Sec., Dr. J. Earl McIntyre, 203 Hollister Bldg., Lansing.

MINNESOTA: * Minneapolis, June 21-23. Sec., Dr. Julian F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul 2.

MISSISSIPPI: Jackson, June 21-22. Asst. Sec., Dr. R. N. Whitfield, State Board of Health, Jackson.

MISSOURI: *Examination*. St. Louis, May 30-31 and June 8-10. Exec. Sec., Mr. John A. Hailey, Box 4, Jefferson City.

MONTANA: Helena, Oct. 3-5. Sec., Dr. Otto G. Klein, First National Bank Bldg., Helena.

NEBRASKA: * *Examination*. Omaha, June 6-8. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Building, Lincoln 9.

NEW HAMPSHIRE: Concord, Sept. 8-9. Sec., Dr. J. S. Wheeler, 107 State House, Concord.

NEW JERSEY: *Examination*. Trenton, June 21-24. Sec., Dr. E. H. Hallinger, 28 West State Street, Trenton 8.

NEW YORK: Albany, Buffalo, New York and Syracuse, June 28-July 1. Sec., Dr. Jacob L. Lochner, 23 South Pearl St., Albany.

NORTH CAROLINA: *Examination*. Raleigh, June 23-25. Sec., Dr. Ivan Proctor, 226 Hillsboro St., Raleigh.

NORTH DAKOTA: * *Written*, Grand Forks, July 5-7. *Reciprocity*, Grand Forks, July 8. Sec., Dr. C. J. Glaspel, Grafton.

OHIO: *Examination*. Columbus, June 15-18. *Endorsement*, Columbus, July 5. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: * Oklahoma City, June 8-9. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

PENNSYLVANIA: *Examination*. Philadelphia and Pittsburgh, July. Acting Sec., Mrs. B. G. Steiner, 351 Education Bldg., Harrisburg.

PUERTO RICO: San Juan, Sept. 6-10. Sec., Dr. Luis Cueto Coll, Box 3717, Santurce.

RHODE ISLAND: * *Examination*. Providence, July 7-8. Chief, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

SOUTH CAROLINA: *Examination*. Columbia, June 27-29. *Endorsement*. Columbia, June 27-28, Aug. 1, Sept. 5 and Oct. 3. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

SOUTH DAKOTA: * *Examination*. Pierre, July 19. Sec., Dr. G. J. Van Heuvelen, Capitol Bldg., Pierre.

TEXAS: *Examination*. Austin, June 16-18. Sec., Dr. M. H. Crabb, 209 Medical Arts Bldg., Fort Worth 2.

UTAH: *Endorsement*. Salt Lake City, May 25. *Examination*, Salt Lake City, July 13-15. Sec., Dept. of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

VERMONT: Burlington, June 21-23. Sec., Dr. F. J. Lawliss, Richford.

VIRGINIA: *Examination*. Richmond, June 17-18. *Reciprocity*. Richmond, June 16. Dr. K. D. Graves, 631 First St., S.W., Roanoke.

WASHINGTON: * Seattle, July. Sec., Mr. Edward C. Dohm, Department of Licenses, Olympia.

WISCONSIN: * *Examination*. Milwaukee, June 28-30. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

WYOMING: Cheyenne, June 20. Sec., Dr. Franklin D. Yoder, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ALASKA: Feb. 1950. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

ARIZONA: Tucson, June 21. Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

COLORADO: *Examination*. Denver, June 1-2. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

CONNECTICUT: New Haven, June 11. Exec. Asst., State Board of Healing Arts, Miss Mary G. Reynolds, 110 Whitney Ave., New Haven 10.

FLORIDA: *Examination*. Gainesville, June 11. Sec., Mr. M. W. Emmel, University of Florida, Gainesville.

MINNESOTA: Minneapolis, June 7-8. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis.

OREGON: Portland, June 18, Sept. 3 and Dec. 3. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

SOUTH DAKOTA: Vermillion, June 3-4. Dr. G. M. Evans, 310 E. 15th St., Yankton.

TENNESSEE: Memphis, July 8-9. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

WISCONSIN: Milwaukee, June 4, Sept. 24 and Dec. 3. Sec., Prof. W. H. Barber, Ripon College, Ripon.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Evidence and Procedure in Reviewing Board's Revocation Order.—The state department of health, on recommendation of the medical examining board, revoked the plaintiff's license to practice medicine in the state of Connecticut. The order of revocation was sustained by the superior court, so the plaintiff appealed to the Supreme Court of Errors of Connecticut.

The only question presented by this appeal, said the Supreme Court of Errors, is whether the state medical examining board acted properly in determining and recommending that the plaintiff's certificate of registration to practice medicine and surgery should be revoked, since such a recommendation was mandatory on the state department of health.

The original complaint against the plaintiff was made to the board by the commissioner of health and charged, on information and belief, that the plaintiff had treated Norman Dombriis "in a fraudulent, dishonorable, unprofessional and incompetent manner." Notice was given the plaintiff and he was summoned to appear before the board at a designated time for a hearing. Prior to the hearing, plaintiff's counsel wrote the counsel for the board, asking for a more specific statement of the charges and received a "Summary of Complaint." It stated that the plaintiff had operated on Dombriis for a fissure and had charged \$150, ultimately reduced to \$125, which Dombriis paid; that Dombriis said "his bowels did not move for four days," so he consulted another physician and surgeon and was told that he still had the fissure; that he was taken to a hospital where he was operated on, and that the charge made for that operation was \$50 with an additional \$12 for hospital visits. A hearing was subsequently held before the board, which voted to sustain the charge that the plaintiff treated Dombriis "in a fraudulent, dishonorable, unprofessional and incompetent manner," and to recommend to the state department of health that the plaintiff's certificate of registration be revoked. In the recommendation submitted to the department of health, the board incorporated a statement that its action "was based on certain subordinate facts adduced from the testimony at the hearing" and detailed its conclusions as to the conduct of the plaintiff in this way: "Fraudulent treatment" in that he informed or implied to Dombriis that he had corrected the diseased condition of the rectum when he had not done so; "dishonorable treatment" in that he had insisted on the payment of an exorbitant fee for services to be considered scarcely more than an office treatment; "unprofessional treatment" in that throughout the treatment he had behaved in a manner not compatible with the established standards of medical professional conduct in this state; and "incompetent" in that his background and training did not justify his claim and statement that he was a specialist in the treatment of diseases of the rectum, that he did not precede the treatment with an enema and neglected to sterilize a speculum used by him in the operation, and that he did not perform the relatively simple procedure which was indicated for the relief of the condition in question and which when later followed by a skillful and competent surgeon resulted in its eradication. The plaintiff objected when, on the trial of the appeal, the recommendation of the board containing these statements was offered in evidence.

The statute, said the Supreme Court of Errors, contains no requirement that the board shall make a finding of facts on the basis of which it acted. In similar cases of appeals from zoning boards, however, we have said that, while a finding of the facts on which the board acted was not required by the statutes, "a full and complete statement in the minutes of the board's action, made with such particularity as to enable the court on appeal to clearly understand what was done, is highly desirable." In this instance the board, instead of including in its minutes the grounds of its decision, incorporated them in the recommendation it made. The statement was properly before the court to enable it to understand the basis of the board's action.

The basic claim of the plaintiff was that the decision of the board involved certain conclusions which no evidence offered at the hearing supported but which the board reached on the basis of its own understanding of the obligations of the plaintiff as a medical practitioner.

The statutes, said the court, provide that the medical examining board shall consist of five members, that the Connecticut Medical Society shall each year file with the governor the name of one physician practicing in this state whom it recommends as competent to serve on the board and that the governor shall appoint the person so recommended for a term of five years. In providing this method of appointment the legislature undoubtedly intended that the membership of the board should consist of men fitted by training and experience to perform the duties and responsibilities imposed on it. We would presume, the court continued, even if we did not know, that the men composing the board were themselves qualified to decide whether certain conduct of a physician or surgeon so derogated from professional standards as unreasonably to jeopardize the interests of the public; and on that basis they were entitled to act. Where a court has been called on to determine the reasonable value of the services of an attorney, we have said: "Courts have a general knowledge of what would be reasonable compensation for services which are fairly stated and described. That knowledge they may apply in considering the testimony of experts on this subject. They will not be bound by the experts' estimate." The same principle applies to the medical examining board. Expert opinions of other physicians offered before it could have been disregarded by it, and from a practical standpoint would in all probability have had little, if any, effect in bringing it to a decision at variance with its own conclusion on the question whether or not the conduct of a practitioner had been compatible with professional standards or whether or not he was competent. With the facts of that conduct before it, the board was competent to determine such questions without hearing expert medical evidence. So in this case, as we must presume the members of the board to have been competent to determine the issues on the basis of their own knowledge and experience, we are confirmed in our conclusion that it was not necessary that expert evidence should be offered before the board.

This brings us to a consideration of the right of appeal from the board given by the statute, said the Supreme Court of Errors. The amicus curiae maintained that the court had plenary power to determine de novo whether the certificate should be revoked. On an appeal from an administrative board, we have repeatedly stated that the function of the court is to determine whether or not the board acted illegally. Under the division of powers between the branches of government provided in our constitution, administrative functions as such cannot be vested in the courts. The revocation of a certificate of registration granted to a physician and surgeon is just as much an administrative matter as is the original grant of it. Neither directly nor in the guise of an appeal can authority be vested in a court to determine on its independent judgment the question whether or not a certificate should be revoked; the court can act only in so far as judicial questions are involved, and it can review administrative action only so far as to determine whether any illegality has entered into it. Where on an appeal the court hears evidence, it is solely for the purpose of determining that question.

Under our procedure, one appealing from the action of an administrative board under a statute which does not otherwise provide may, if the record before the board does not sufficiently disclose the basis of its action, offer evidence before the court as to the facts and the court will act on the assumption that they were the basis on which the board reached its decision. On an appeal from the medical examining board, if no expert evidence was offered before it, the appellant may produce such evidence and the court would then test the decision of the board in the light of it.

For these, and other, reasons the Supreme Court of Errors concluded that no error existed in the trial court's finding and the judgment of revocation of the plaintiff's license was accordingly affirmed. *Jaffe v. State Department of Health, 64 A. (2d) 330 (Conn., 1949).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Juxtaglomerular Apparatus of Hypertensive Kidney. J. Des Prez Jr.—p. 953.

Nonerythroblastic Hydrops Fetalis.—Bromberg and Polishuk point out that it is generally accepted that hydrops fetalis represents one of the clinical forms of hemolytic disease of the newborn. In almost all cases of hydrops fetalis recently reported in the literature, incompatibility in the Rh factor between mother and fetus as well as signs of maternal immunization have been observed. Before the discovery of antigenic incompatibility between mother and fetus as the cause of erythroblastosis fetalis, hydrops fetalis was related to various causes, such as fetal malformation and toxemia of pregnancy. The authors present the case of a woman who delivered 2 hydropic infants in her first and fourth deliveries, while her other two pregnancies terminated in the delivery of normal children. Antigenic incompatibility between mother and fetus could be excluded. No maternal immunization or signs of fetal erythroblastosis were found. Both pregnancies which terminated in the delivery of hydropic infants were associated with a severe toxemia of pregnancy, while the other pregnancies had a normal course. The fact that hydrops fetalis occurred unassociated with erythroblastosis leads to the assumption that two forms of hydrops fetalis exist: an erythroblastic and a nonerythroblastic form. This case indicates that the nonerythroblastic hydrops fetalis may be related to toxemia of pregnancy.

Cataract Extraction by Suction Method: Review of 75 Cases. C. I. Thomas.—p. 805.

Fundus Changes Associated with Pheochromocytoma.

Bruce reviews the literature on pheochromocytoma, giving particular attention to ocular changes. The dominant symptom in patients with this tumor is vascular hypertension, in the course of which pathologic changes may be found in the retina or in its blood vessels or in both. The findings cannot be differentiated ophthalmologically from those encountered with hyper-

tensive vascular disease ("essential hypertension"). Because the ocular symptoms may be the first or the only sign of the disease, the ophthalmologist will often be seen before the internist. The possibility of pheochromocytoma should be considered whenever he finds evidence of vascular disease. The 3 cases reported in detail concerned children with pheochromocytoma, all of whom had pathologic changes in the retina.

Penicillin in Ocular Diseases.—Von Sallmann presents a survey of the subject of ocular penicillin therapy. He reviews problems involved in the parenteral use of penicillin and its surface application by solutions and ointments and by iontophoretic introduction. Local injections of penicillin under the conjunctiva, into the anterior chamber, into the lens and into the vitreous are discussed.

Treatment of Tetanus.—Smathers and Weed formulate a plan of treatment which is based on a study of 86 cases of tetanus. The patient on admission is given cutaneous conjunctival tests with tetanus antitoxin diluted 1:100. If sensitivity is present, desensitization is attempted or "despeciated" antitoxin is given. If a wound can be found, 50,000 units of antitoxin is given intravenously and 10,000 units locally around the wound. If no wound is found, the entire contents of three 20,000 unit vials is given intravenously. As soon as the sensitivity test is given, 1 cc. of d-tubocurarine in wax and oil is administered intramuscularly. For immediate control of convulsions, purified chondrodendron tomentosum extract (intocostrin®) may be given intravenously, but the authors prefer to remove the patient to the operating room for ether anesthesia. With the patient anesthetized, 20,000 units of tetanus antitoxin is injected intrathecally and the wound debrided. Oxygen, a laryngoscope, an endotracheal tube and aspirating apparatus are available at the bedside after the operation. Penicillin is given every three hours to prevent respiratory infection and for its action on infected wounds. Penicillin, has no apparent effect on the toxin of *Clostridium tetani* and no proved clinical effect in the treatment of generalized tetanus. Five thousand units of tetanus antitoxin is given daily for five days if the infected focus has been removed, longer if the focus cannot be found. D-tubocurarine in wax and oil is given intramuscularly daily according to the clinical response of the patient. Patients must be watched constantly by experienced personnel in order that possible curare toxicity may be coped with immediately.

Fat Embolism, a Diagnostic Enigma.—Denman and Gragg state that reports about the incidence of fat embolism vary greatly. In their series of 99 necropsies selected at random, there were 7 cases in which the condition was of sufficient severity to be considered the primary cause of death. In an additional 24 cases fat emboli were present but were not

judged sufficient to account for death. There is usually an association with trauma to adipose tissue, particularly that in the osseous system; in a number of cases the condition has been reported to follow injury to the subcutaneous tissue and fatty viscera. Fat embolism causes a slowing of blood flow through a capillary bed, while oil droplets become elongated and are slowly forced from the arterial to the venous side of the circulation to become lodged in the capillary bed of all the organs. Elimination of fat emboli may occur by escape from renal glomeruli into the urine; excretion by the liver into the bile; phagocytosis, and emulsification by the mechanical action of the blood current perhaps aided by the saponifying action of blood lipase. The onset of fat embolism may be sudden, but usually symptoms become manifest after the third or fourth day and in the cardiorespiratory type may consist of dyspnea, cough, frothy sputum with occasional hemoptysis, cyanosis, precordial pain, cardiac dilatation, elevation of temperature and often asthmatic or bronchopneumonic type rates. In the cerebral form symptoms are variable and include loss of memory, disorientation, restlessness, irritability and occasionally convulsions, which later give way to drowsiness, stupor and, finally, coma. The best treatment is prevention and consists of avoidance of rough handling of patients, immediate splinting, early reduction and fixation of fractures, the use of a tourniquet during operations on fatty marrow and the avoidance of fat solvent anesthetics. Suggested methods of treatment are the injection of sodium bicarbonate or bile salts, venesection, drainage of the thoracic duct, venous ligation, incision of the injured site to relieve pressure and to remove blood and fat and even amputation. Pituitrin, caffeine, nikethamide, morphine and insulin have been suggested because they have been found to cause a steady fall in the level of blood fat. The administration of oxygen is beneficial. Clinicians must think of fat embolism, particularly in injured patients. The dark field examination of the blood and the urine "sizzle" test seem to offer the most promise of corroborating the diagnosis of fat embolism.

Results of Vagus Resection in Peptic Ulcer.—Miller and Olwin attempt to evaluate results in a series of 101 patients subjected to vagotomy in the past two and a half years. For the most part these 101 patients had a long-standing chronic peptic ulcer which had failed to respond to a medical regimen. In more than half the duration was over ten years. In 87 the lesion was in the duodenum. In 47 there was a history of bleeding; 26 had had perforations, and in 36 obstruction was demonstrable. The transthoracic approach was employed in 29 and the abdominal approach in 72 patients. The postoperative course was usually smooth. The Levine tube was left in place three or four days. Early ambulation was encouraged. A few patients had a mild pleural effusion and pain in the chest for several days, but in only 1 instance was it a prominent feature in the months following operation. One woman had trouble swallowing for almost a week, and 1 had a paralytic ileus, but this passed away. Fulness in the abdomen was a common temporary complaint, but diarrhea was the most obstinate. It was present in 39 patients, being temporary in 30, prolonged for several months in 2 and persistent in 7. There have been no deaths. Nine patients had left Chicago and could not be traced, which leaves 92 in whom follow-up was possible. In 76 of these the results were good, in 13 they were fair, and in 3 poor.

Testosterone Propionate in Cancer of Breast.—McGraw says that 12 women under care at the Henry Ford Hospital for breast cancer, recurrent after radical operation, were given testosterone propionate and the resulting effects were closely watched. Individual doses were mostly 150 mg. Aggregate total doses were from 450 to 6,225 mg. Injections were intramuscular in alternate buttocks. Given slowly, they have not produced pain, soreness or any late untoward local reactions. Only in the first 2 patients treated were there objectionable general reactions to the drug, and those were the result of unnecessary large initial doses. There have been slight masculinizing effects in 3 patients, principally of the voice, none sufficient to create a problem. Of the 12 patients treated, 6 have died, but only 1 failed to show some beneficial clinical response.

In 6 of the 12, clinical improvement was striking, in 2 good and in 3 fair. The author concludes that although testosterone propionate does not cure cancer, its use as a palliative agent has a logical basis, and its beneficial effects are such as to encourage further use and study. Best results with respect to duration of palliation have been in patients whose metastases have been principally or solely in bone. Testosterone propionate is an adjunct to, not a substitute for, roentgen therapy.

Carcinomas in Hybrid Mice Treated with Estrogen or Androgen.—Two groups of reciprocal hybrid mice were used in the experiments by Pan and Gardner, PC₁ and PC₂. Of 57 female mice of group PC₁, 14 received estrogens and 43 were untreated controls. Ten of the 14 treated mice lived for more than two hundred days and are included in this study. Of the 70 female mice of the PC₂ group, 31 received steroid hormones and 39 were untreated. Twenty-five of the treated mice survived two hundred days or more and are included in this study. The hormone-treated mice received estradiol benzoate or diethylstilbestrol or estradiol benzoate plus testosterone propionate. Four of 10 estrogen-treated hybrid mice that tolerated the treatment more than two hundred days had carcinomas of the uterine cervix or vagina. Nine cervical carcinomas or invasive epithelial lesions were observed among 25 treated hybrids that survived two hundred days or more. All the 13 tumors were epidermoid carcinomas or invasive epithelial lesions that were considered to be early stages in tumor formation. None of the 82 mice in the control groups had carcinomas of the uterus or vagina, although 5 had uterine fibromyomas. In association with the neoplastic change of the uterine and cervical tissue, chronic proliferative vascular lesions have been observed involving the parametrial and uterine vessels.

Urinary Porphyrins in Lead Poisoning.—Meek and his associates regard quantitative enumeration of basophilic stippled erythrocytes as a fairly laborious and time-consuming technic and one that is not entirely specific. The basophilic aggregation test of McCord, while no more specific, has proved to be a valuable refinement; it is relatively simple and saves time. Good correlation between the basophilic aggregation test and urinary lead excretion has been demonstrated in the case of certain lead salts soluble in human pleural fluid and blood serum. It does not correlate in "old" cases of lead poisoning. The urinary porphyrins have been given considerable attention with reference to lead poisoning. The hope is expressed that as knowledge of porphyrin metabolism increases, a simple test may be evolved which will give an early indication of lead absorption and/or lead poisoning. The following report does not reveal such a test, but it is hoped that it will stimulate interest in this approach. Single voidings of urine were obtained from 66 workers exposed to lead fumes. The lead content was determined on a portion of each sample. The semiquantitative urinary porphyrin test of de Langen and ten Berg was performed on another portion. There were 31 positive results among 66 lead-exposed workers. The rapid evaluation of present or potential lead intoxication by means of the determination of porphyrins in urine is subject, as is stippling or basophilic aggregation, to the influence of a number of other chemicals. It is not directly dependent on any blood dyscrasia. It represents potentially a laboratory tool which can represent with much greater fidelity the various forms of lead intoxication than could stippling methods.

- Pathology of Bone Tumors. M. C. Wheelock.—p. 522.

What Causes Gas?—Alvarez has studied the question of what causes flatulence for thirty-five years. It involves interference with the normal absorption of gas from the bowel. Much of the gas in the bowel is swallowed air. Much appears to come out suddenly from the blood. Some is formed during digestion. In the healthy person gas formed in the bowel is rapidly picked up by the blood and excreted by the lungs. The three main gases in the bowel are nitrogen, oxygen and carbon dioxide. The first causes the most distress because it is absorbed slowly. Gas or swallowed air goes through the bowel rapidly and painlessly if there is no spasm anywhere. Spasm is more likely to be associated with the gas produced by food allergy. The physician must make sure what the patient means by "gas." Does he belch, or bloat or pass gas? Belching often repeated is a neurosis associated with the swallowing of air. There is also a pseudobloating, hysterical in nature, and not due to gas. True bloating can be due to eating, to being hurt physically, to taking a nap or to constipation. An excess of flatus may be due to swallowing air, to indigestion, to constipation or to eating more food than the bowel can handle or to eating certain gas-making foods. Flatulence can be produced by any disease that interferes with the circulation or with the functions of the liver or the lungs. It is seen with cholecystitis, diarrheas, duodenal ulcer, constipation, hemorrhoids, intestinal obstruction, mucous colics and the eating of a rough or flatulent diet. Drugs fre-

quently fail in the treatment. A patient may be helped with a smooth diet, a light diet or diet without foods to which he is allergic. Some persons are relieved if they keep the colon clean with enemas.

- Turner's Syndrome. R. B. Greenblatt and H. E. Nieburgs.—p. 993.

Intoxication with Vitamin D.—Howard and Meyer feel that despite publicity in the medical literature on the dangers associated with the administration of large doses of preparations of vitamin D, there are still many physicians who use these drugs without the precautions necessary for substances potentially so toxic. During the past three years the authors have seen 11 instances of intoxication by such sterols. Ten of these patients had been given the drugs by physicians who were not aware that the alarming symptoms exhibited were related to the therapy which they themselves were prescribing. The eleventh patient was one in whom the authors themselves induced hypercalcemia with calciferol (crystalline vitamin D₂) within fourteen days. Most of the patients had anorexia, nausea, vomiting, weakness, fatigue and lassitude. In every instance weight loss and fatigue had been noted prior to anorexia and vomiting, and these are, therefore, considered the main symptoms of intoxication with vitamin D. Despite careful search only one of the patients showed evidences of gross vicarious calcification in periarticular, subcutaneous or renal tissues. However, the characteristic eye lesions described by Walsh and Howard were seen in nearly all patients. These lesions are visible by slit lamp examination, and the deposits beneath the conjunctival basement membranes are thought to be calcium salts. All patients, when first seen by the authors, had renal insufficiency. The only therapy prescribed was cessation of drug administration, forced fluids and a diet low in calcium. Subjective improvement occurred within two to eight weeks after instituting this regimen, even in those who showed but small objective improvement. The authors present 2 of the 11 case histories. They believe that hypercalcemia is largely responsible for the symptoms and signs of vitamin D poisoning. Patients to whom these drugs are administered should be followed by frequent slit lamp examination, urinary analyses and determinations of the serum calcium.

A Geriatric Group in a General Hospital.—According to Zeman the general hospital is caring for an increasing number of older men and women who present not only complex medical problems but also a variety of social and economic problems. To serve these aged persons more effectively, he suggests that a special geriatric group be organized in each large hospital to study their medical, surgical and psychiatric needs. It would function in the hospital wards and in the outpatient department and would integrate the work of the general hospital with that of other health and welfare agencies. Through this group's activities the older patients would receive better care and would find their hospital sojourn a far happier experience.

Solar Urticaria.—Beal says that in solar urticaria a brief exposure of the skin is followed in a few minutes by development of intense itching and erythema confined exactly to the areas exposed to the sunlight. A few minutes later, small islands of wheals form in the erythematous area and in a short time coalesce to form a continuous urticarial wheal limited to the exposed area. As the urticarial edema develops, a flare of diffuse erythema occurs around the wheal in the unexposed skin. According to the intensity of exposure it lasts from half an hour to several hours. The author presents studies made on 2 patients with solar urticaria. Both were women, aged 42 and 30, respectively. Their spectral sensitivity was established by use of glass filters and monochromator. The range of sensitivity was found to be between 2,967 and 3,341 angstrom units, with a maximum at 3,131 angstrom units. The urticarial sensitivity could be passively transferred by injecting the patients' serum into the skin of normal persons and irradiating the injection site with the active wavelengths. Antihistaminic drugs were found to be protective against the urticarial reaction, and by virtue of this protective action it was possible to subject these patients to gradually increasing ultraviolet exposures. Eventually the skin acquired enough tolerance to the active wavelengths and it was possible to discontinue the use of the antihistaminic substances.

Self-Inflicted Prefrontal Lobotomy.—Papez and Smolen report the case of a man, aged 63, who attempted suicide by shooting himself in the right temple with a revolver. After nine weeks of hospitalization he was admitted to the Columbus State Hospital because of the residua of his injury. An attempt was made to deduce the reasons for the attempted suicide by an evaluation of the patient's personality difficulties and the cortical degenerative changes, both of which were related to the patient's chronic alcoholism. Neurologic findings were minimal, and could be related to the proximity of the path of the bullet to the middle frontal gyrus. The chief defects seemed to be in the higher mental functions; the ones usually ascribed to the prefrontal areas. The patient's postoperative course roughly resembled that seen in prefrontal lobotomies. The recovery was much slower, not so steadily progressive and not nearly so complete. This was not unexpected because of the much greater violence, the increased destruction of brain tissue and the more profuse hemorrhage. At the time of this report the patient was neat and clean, and was able to find his way around the ward. He was content to be by himself and made no effort to mingle with the other patients. He showed placidity, mild euphoria and some confusion and inappropriate outbursts of laughter or crying. The psychologic tests revealed loss of

abstracting and generalizing ability, disturbances of voluntary attention, easy distractibility and impaired memory, as well as disturbance of associative processes. He showed no concern for the future, and his ideation was extremely limited. He manifested the typical picture of impaired functioning of the prefrontal lobes.

Acute Porphyria.—Clark and Lawrence report a woman, aged 19, who was hospitalized with complaints of nausea, vomiting and mental changes of three weeks' duration. On the fourth hospital day she began experiencing cramplike pains in the abdomen and musculature of the upper arms and legs, became disoriented, confused and later comatose. At this time her urine was first observed to have a deep wine red color which became darker on standing or exposure to sunlight. The urine was found to contain an abnormally large amount of ether-soluble porphyrins (coproporphyrin). Porphobilinogen was also present. The clinical course following diagnosis consisted of remissions and exacerbations of her presenting symptoms during which a Landry type of ascending paralysis developed, advancing to a complete quadriplegia and bulbar involvement necessitating at one point the use of a Drinker respirator. She died on the seventy-second hospital day. The authors suggest that porphyria may occur more frequently than is realized. The patients may be subjected to needless abdominal surgery, to hospitalization in a psychiatric ward for a supposed functional psychosis, or to both. Any acute abdominal illness with little or no abdominal tenderness should make one suspect this disease. The addition of psychiatric symptoms, neurologic signs, or both, is almost diagnostic. Patients presenting this picture should be questioned about the color of the urine. The urine may be examined with Ehrlich's reagent, which produces a wine color in urine containing abnormal amounts of porphyrins. Among the conditions to be differentiated are the Guillain-Barré syndrome, tick paralysis, poliomyelitis, familial recurrent and familial periodic paralysis, serum paralysis, parotitic paralysis and periarteritis nodosa (Hoagland). Therapy is symptomatic and supportive.

Schistosomiasis Japonica Diagnosed by Rectal Biopsy.

—Zieve and Conley say that practically all of the cases of schistosomiasis in the armed forces during the last war were acquired in the Philippine island of Leyte. Approximately 1,500 patients were treated while in the service, and it is estimated that in an equal number, less severely infected, the disease went undiagnosed. The case reported illustrates the need for alertness to the possibility of schistosomiasis in a veteran who has been on Leyte. During repeated examinations scrapings of the anal crypts and rectal mucosa were examined for ova without success. A complement fixation test with schistosome antigen was negative, and a skin test with mixed schistosome antigen also was negative. Finally, four pieces of tissue were removed, one of which contained ova of *Schistosoma japonicum*. Therapy with antimony potassium tartrate was instituted, a total of 444 cc. of a 0.5 per cent solution of antimony and potassium tartrate (0.799 Gm. antimony) being given over a period of five weeks. The patient noted appreciable relief from his pain

in the right upper quadrant. Rectal biopsies were repeated, fragments being taken from each of the three valves of Houston. The fragment from the uppermost valve showed submucosal pseudotubercles with nests of encapsulated ova similar to those seen at pretreatment biopsy. The other two fragments were normal. The patient remained asymptomatic. His liver was no longer tender. The white blood cell count returned to normal levels. His whipworm infestation was successfully treated. He was discharged during the fifteenth week of his second admission, twenty-three weeks after he was first hospitalized. The classical description of schistosomiasis has been based on observations in native populations where multiple parasitic infestations, reinfection and nutritional deficiencies are common. It seems logical to expect that the course among well nourished American soldiers, who were usually exposed a relatively short time, should be different. The present patient, despite the prolonged course, recurrent clinical manifestations and lack of treatment, appeared well nourished and, with the exception of the periods when diarrhea recurred, was able to keep up his farm duties. The authors stress the diagnostic importance of rectal biopsy.

Generalized Bullous Eruption Following Testing for Sulfonamide Hypersensitivity.—According to Straus, the bullous eruptions that may result from sulfonamide toxicity are often clinically indistinguishable from idiopathic erythema multiforme exudativum. The author reports a case which demonstrates the importance of establishing or excluding the sulfonamide compounds as etiologic agents when the possibility of their future therapeutic use is considered. Although the patient gave no past history of exposure to a sulfonamide drug, the onset of fever followed by the eruption and conjunctivitis which occurred on the second day (rather than after seven or ten days) of sulfonamide therapy in December 1947 suggested previous sensitization to the drug. In retrospect, it might be conjectured that the "erythema multiforme" reported from 1945 followed the use of the drug at that time. The history of this patient also illustrates the unreliability of the patch test, an untoward and at first unrecognized reaction to the intradermal

passive transfer test and a severe reaction following an oral test dose of sulfonamide compound. It is believed, therefore, that testing for sulfonamide sensitivity should be approached with care, as should the treatment of erythema multiforme exudativum with sulfonamide compound, unless it is certain that this drug is not the etiologic agent.

Kerosene Poisoning.—Bologna and Woody say that at the Charity Hospital in New Orleans for the ten year period 1937 to 1947 there were 252 records of kerosene ingestion by children. Ages ranged from 5 to 72 months, and 97 per cent of the patients were between the ages of 6 and 36 months. These figures illustrate the fact that this, like most accidental poisonings, is most frequent in the toddler or runabout age. There were 9 deaths among these 252 patients, a fatality rate of 3.6 per cent. Effects on the pulmonary and nervous systems dominate the picture and evidences of gastrointestinal disturbances are relatively inconspicuous. Everything points to pulmonary irritation and edema as the principal cause of death. Rational therapy of kerosene poisoning should have as its chief objective the prevention or amelioration of pulmonary edema. Though the mechanism of the production of pulmonary edema is poorly understood, absorbed kerosene may play some role; the authors have seen pulmonary edema improve after removal of kerosene from the stomach and they have seen children who experienced severe respiratory distress only after they had fought, gagged, struggled and undoubtedly aspirated during ill timed attempts at lavage. Whenever it is possible to do so without increasing dangers of aspiration the stomach should be lavaged. The only other therapy which holds promise is the administration of oxygen, since death in pulmonary edema is due, literally, to drowning. Use of antibiotic and chemotherapeutic agents may be indicated to prevent or treat pneumonia or other respiratory infections. Hyperventilation and postural drainage may be instituted for atelectasis and as prophylaxis against later bronchiectasis. Such measures are begun only after the twelve hour damage has passed.

Visualization and Photography of Uterine Canal.—Norment points out that submucosal myomas and polyps are sometimes difficult to diagnose by palpation or curettage, but when an opaque dye is instilled into the uterine canal, they are usually easily seen on a roentgenogram. He discusses the filling defects produced by polyps, myomas and cancers. A hysteroogram can be made in the office and, unless there is severe constriction of the cervical canal, it causes little discomfort. It is preferable that the dye be injected into the uterine canal when the patient is not bleeding. If the patient is bleeding

continuously, the author attaches a light rubber tissue bag to a catheter and instills the dye through the bag. This method, however, requires dilation of the cervix with the patient under anesthesia. In cases with filling defects in the hystrogram, the author uses a new lens hysteroscope for direct visualization of the interior of the uterine canal. By this combination of roentgen examination and direct inspection, diagnosis of pathologic lesions in the uterine canal is made much more accurate. The author describes the construction and operation of the instrument that he has devised for hysteroscopic examination. A reproduction of a photograph made by the camera that can be attached to the optical system of the hysteroscope shows the interior of the uterus. Through the hysteroscope a carcinoma is seen as a whitish gray growth against a red background. In a few cases of carcinoma of the fundus that the author observed through the hysteroscope there was no doubt about the presence of a malignant growth. In doubtful cases a curettage is the only safe way to determine the presence or absence of a carcinoma.

Camoquin® in Malaria.—Ejercito and Duque report on the use of a new synthetic drug originally known as CAM-AQ. It has the chemical name 4-(7-chloro-4-quinolylamino)-alpha-diethylamino-ortho-cresol—it is known also as camoquin® and is dispensed in 0.05 Gm. tablets of a light yellow color. The authors have used this drug in 128 patients with malaria at the San Lazaro Hospital, Manila. Eighty-four patients had vivax malaria and 44 the falciparum type. In the vivax malaria, fever and peripheral blood parasites usually disappeared after the third or fourth day. In afebrile patients the parasites disappeared on the second day. In patients with the falciparum type of malaria fever disappeared on the third to the fifth day, the asexual parasites between the second and fourth days and the sexual parasites between the ninth and the nineteenth day. The drug seems to have slight or no effect on the crescent forms, but it has a decided effect on the vivax gametocytes and on the asexual forms of both vivax and falciparum malaria. Ten of the patients had a relapse; these belonged chiefly to the group with the vivax form. The drug caused no undesirable secondary effects.

Q Fever and Milk.—Jellison and his associates point out that the recovery of Q fever organisms from the raw milk of four dairies in Los Angeles County was reported previously. The strains isolated were identified by all accepted criteria as *Coxiella burnetii*. Subsequently, samples of raw milk from other

dairies and from many cows in the same area were found to be infectious. The possibility was considered that Q fever organisms might persist in milk products that are not subjected to pasteurization or cooking. Test animals given injections of fresh milk, freshly churned butter and buttermilk all survived and were bled in thirty days. The serums were tested for Q fever antibodies and all were positive at high titer. Of the two test animals given injections of butter after it had been stored forty-one days at below freezing temperature, one died on the ninth day of test from undetermined cause. The other was bled on the thirty-second day and the serum sample was positive at high titer. Of the 8 animals given injections of butter at the Rocky Mountain Laboratory, 3 died before the end of the test period; 1 was killed for transfer, and a strain of Q fever was established. The 4 remaining animals were bled on the twenty-ninth day after injection, and all serums were positive at high titer.

"Precancerous Conditions" of Breast.—Dawson defines cancer as the terminal stage of a long proliferative process which eventually produces a malignant tissue. Precancer, in the strict sense of a cause-effect relationship, implies the stages before actual malignancy emerges; i. e., a condition or conditions which will go on to cancer, even when the carcinogenic agent is withdrawn. There is no lesion in the breast, or in any tissue of which one can say, "this will inevitably become carcinoma." In cancer, one is dealing not with one but with several unknowns—the carcinogenic agent itself, the mechanism by which it produces malignant cells, the stages through which the cells pass in this transformation and the time factor; there is also, possibly, an ill defined, genetic organ or tissue susceptibility. Thus the term "precancer" can be used only in the sense of antecedent lesions which may later emerge as cancer. Adenosis as such does not lead to carcinoma; neither does the blue dome cyst; the majority of fatty cysts also eventually become quiescent, but with the fatty cyst, and in ducts with fatty contents or fatty degeneration of proliferated epithelium but little dilatation, there is always the possibility of the formation of a progressive epitheliosis which may become definitely malignant. One or two implications, rather than conclusions, seem justified: 1. The pathologist should not be expected to give a dogmatic report on a small piece of tissue excised from a suspected mammary lesion. With local excision of the clinically obvious abnormal area, there is no guarantee of what is happening or may happen in the rest of the breast. Relevant data in the patient's reproductive history are helpful in the interpretation of many hyperplastic appearances, at any age. 2. Examination of suspected lesions of "chronic mastitis" type, as the breast is approaching the cancer age, shows a tissue instability suggestive of a to and fro struggle between a degeneration which gradually destroys much of the glandular structure, often with residual cyst formation but with later permanent quiescence, and a proliferation which becomes progressively

atypical and eventually cancerous. The author believes that the concept of a sudden development of carcinoma of the breast can be rejected.

Streptomycin-Sulfadiazine in Undulant Fever.—Scowen and Garrod point out that when two chemotherapeutic agents of partial efficacy are available it is likely that they will have an additive if not a synergistic effect when administered together. A trial of the combined effect of streptomycin and sulfadiazine was therefore indicated in cases of undulant fever. Eisele and McCullough reported 1 case of the disease so treated, and Scowen and Garrod present 2 additional cases in this report. One of these was of several months' duration and the other was recent. Both patients responded to combined treatment with streptomycin and sulfadiazine, the former with a fall in temperature to normal within three days, the second somewhat more gradually, the temperature reaching normal only at the end of the course. They have now been afebrile for six and two months, respectively. These observations confirm American reports of the efficacy of this treatment.

Early Ambulation in Obstetric and Gynecologic Cases.—According to de Soldenhoff there is considerable variation in what is meant by early ambulation. In the United States it means getting out of bed in the first twenty-four hours after operation or delivery. In some parts of Europe the patient walks back from the theater or delivery room. To the author early ambulation means to be out of bed on the third postnatal or postoperative day, though occasionally he has followed Leithauser's technic of making the patient stand by the bedside and cough three or four times within eight hours of operation, particularly where pulmonary complications may be expected. The results of a year's trial of such early ambulation are here compared with those of a previous year in a survey of 2,735 admissions, with 1,878 deliveries. The author found that in cases of cesarean section, myomectomy and other operations that the psychologic response to early rising is most pronounced, particularly in cases of repeat cesarean section in women who previously had been fourteen days in bed. The patients appear to be impressed by their rapid return to normality. Early rising is particularly valuable after an abdominal operation, because the loss of muscular tone is more rapid and the interference with respiration more complete than in any other type of case, and recumbency reduces the vital capacity. The author is convinced that early ambulation does no immediate harm either to obstetric or to gynecologic patients, and it certainly allows a much bigger turnover of patients in hospital. It is hard on the staff, but a physical therapist saves the nurses much work by encouraging patients in their exercises.

Causation of Psoriasis.—Norrlind published in 1947 investigations on the existence of positive agglutination reactions with streptococci in patients with psoriasis. He has continued these studies and has found that, compared with controls, patients with psoriasis show a much higher incidence of positive agglutination with streptococci. He assumes that these agglutination reactions are brought about by past or present streptococcal infections outside of the skin, usually in the respiratory tract. Factors which favor this theory are: Patients with psoriasis rarely have other skin infections simultaneously; positive streptococcal agglutination reactions are twice as frequent among patients with psoriasis as among those with other skin diseases including pyoderma, and respiratory infections occasionally precede the appearance of psoriasis. There are factors which suggest that psoriasis, "psoriasis arthropathica" and chronic, rheumatic polyarthritis are related, possibly in that the infections giving rise to the rheumatic polyarthritis also give rise to psoriasis in persons with a predisposition to this disease. The author calls attention to the fact that patients with arthritis also have a high incidence of positive streptococcal agglutination reactions and that disorders of the joints in patients with psoriasis resemble those in chronic rheumatic polyarthritis. A number of factors may play a part in the onset of psoriasis. One case is cited in which a throat infection, sun bathing, medication with arsenic and pressure from a waist band seemed possible causal factors.

Derris Root as Cause of Occupational Disease.—Simons gives an account of clinical pictures observed in employees of derris mills. In subjects exposed to derris for a considerable period catarrhs and dermatitis usually develop: conjunctivitis (scleritis), rhinitis, pharyngitis, laryngitis, balanitis and posthitis. Eczema may develop on the lips, nostrils and eyelids; also on the scrotum, penis and groin. Other symptoms are loss of taste and appetite, sensation of tongue swelling, headache, nausea and numbness, vomiting, abdominal pain, coma and death. The value of medicinal preparations containing derris is doubtful.

General Condition and Blood Changes Under Influence of Thiouracil and 4-Methyl Thiouracil.—Fischer and her associates studied the general condition and the blood picture of female rats which were treated with thiouracil or with 4-methyl thiouracil. They found that when these drugs were given to young growing rats in daily oral doses of 0.1 or 0.5 Gm. per kilogram of body weight their increase in body weight during twenty-two days of medication was decidedly less than in untreated controls. The resistance to intercurrent disorders was lessened by both antithyroid substances in proportion to the dosage given. The blood picture showed a decrease in the number of leukocytes and immature myeloid cell forms. Nuclear shifting appeared late in the course of treatment or even after treatment had ceased, but it may persist after treatment. It was observed only after the administration of the larger doses, whereas leukopenias were observed even after the 0.1 Gm. doses.

As regards the changes in the blood, there was little difference whether thiouracil or 4-methyl thiouracil was given, but the other secondary effects were more frequent and severe after treatment with 0.5 Gm. doses of 4-methyl thiouracil than after the same dose of thiouracil.

Elastometry in Children with Changing Dilatation of Skin. J. Jochims.—p. 228.
Damage Caused by Mitigal in 2 Infants; Remarks on Effect of Sulfur. W. Ziegler.—p. 237.

Rheumatism in Childhood.—Künstler distinguishes two main types of rheumatism in children, i. e., the specific infectious rheumatism or "rheumatismus verus" and the unspecific rheumatism with cocci as causative agents. Of 137 children with rheumatism who had been treated at the pediatric clinic in Cologne during the period from 1934 to 1941, 127 had specific infectious rheumatism and 10 had unspecific rheumatism. Treatment of the 127 patients consisted of large doses of aminopyrine for six to eight weeks. Children under 8 years of age were given 0.3 Gm. five times daily, and older children received the same dose six times daily. The average total dose of the drug varied from 55 to 70 Gm. This therapy was combined with strict rest in bed and with application of cotton wool packs in the presence of pronounced swelling. Aminopyrine was tolerated well by all the patients. There was not a single case of agranulocytosis after aminopyrine. Fifty of 64 patients with rheumatic arthritis made a complete recovery; there were 13 among the 64 patients who had had recurrences before the treatment and 11 of them recovered. Twenty-one of 41 patients with rheumatic arthritis and carditis recovered, 6 of 16 with recurrences. Four patients of 12 with rheumatic arthritis associated with pancarditis or pericarditis, 2 of 3 with endocarditis and 3 of 7 with pancarditis recovered. Follow-up of 80 patients revealed that permanent cure, prevention of recurrences and a favorable effect on the carditis resulted from this specific treatment provided that it was instituted before the dissemination of the causative agent of the specific infectious rheumatism and before irreversible damage had been caused. Treatment of the 10 patients with unspecific rheumatism caused by cocci consisted of elimination of the focus by tonsillectomy or by dental treatment. Six of the patients recovered.

Question of Dependence of Prothrombin Content of Blood on Menstrual Cycle. H. Bayerle and R. Marx.—p. 767.

Simple Method for Detection of Erythroblastosis in the Newborn.—Dahr places on a slide one drop each of AB serum and of isotonic sodium chloride solution. The two drops should not be applied by means of the same pipet. A trace of blood from the umbilical cord of the newborn infant is brought into the drop of AB serum and also into the isotonic sodium chloride solution. If the umbilical blood is introduced by means of a slide, different corners of the slide should be used for introduction into the two drops. The drops are stirred and spread out until a uniform mixture has been obtained. After about two minutes the slide is rocked back and forth, and this is repeated from time to time. The reaction can be read at the end of twenty minutes. If the blood of the newborn infant contains univalent Rh antibodies, they become activated by the x-protein contained in the AB serum, and as a result a fine granular agglutination is visible, but in the sodium chloride mixture no agglutination is evident. The reaction can be read with the naked eye or with a reading glass; microscopic examination is unnecessary. If no agglutination is visible in the AB serum, either the infant does not have erythroblastosis or, if he does have it, univalent Rh antibodies are lacking. Thus

the method is reliable only if it is positive. It has the advantage that it is simple and rapid. If it is positive, transfusion into the vein of the umbilical cord can be begun at once without waiting for tests on the blood of the parents.

Allergic Dermatitis from Streptomycin in Nurses.—Touraine and Pichon point out that after reports appeared in different countries indicating that in some nurses who handle streptomycin mucocutaneous lesions develop, the public health authorities in France issued a circular drawing attention to this fact and suggested that these disorders might be prevented by having the nurses wear rubber gloves and protective glasses and by excluding from the handling of streptomycin those nurses who are sensitive to it. The sensitivity usually becomes evident after several months of contact with streptomycin. It manifests itself in the form of general malaise, blepheroconjunctivitis and dermatitis on the uncovered parts of the body. These mucocutaneous lesions are generally mild and disappear when contact ceases, but recur when contact is resumed. Since they are due to progressive allergic sensitization, nursing personnel susceptible to them can be detected by cutaneous tests.

- *Epidemic Anemic-Hematuric Syndrome. J. Brage Villar.—p. 649.
*Clinical Diagnosis of Cancer of Lung. G. H. Alvarez.—p. 690.

Epidemic Syndrome of Anemia and Hematuria.—According to Brage Villar, this syndrome was observed sporadically in certain regions of the Province of Entre Rios. Since 1947 it has been epidemic and in apparent relation with the aggravation and subsidence of a regional disease in cows. The disease is more frequent in children than in infants and adolescents and it is rare in adults. The syndrome occurs either in winter or in summer with prodromal symptoms, subacute hypochromic anemia, asthenia, tachycardia, fever and vesiculocrythematosus dermatitis of the body common to both forms. The predominant symptom in both forms is subacute anemia. Mixed forms can be observed. The predominant early symptoms in winter are anemia and renal disorders. Edema, dyspnea, oliguria, hematuria, albuminuria and cylindruria appear in the course of the disease. The predominant symptoms, in summer, are lack of appetite, nervousness, vomiting, fetid diarrhea, gastralgia, jaundice and dehydration. The prognosis is favorable. Early and continuous rehydration of the patient is of importance. The treatment consists in administration of nonmercurial diuretics in patients with renal disorders and antidiarrheal drugs, vitamins, nicotinic acid, liver extract and iron in the enteropathic forms. Sedatives in the presence of nervousness, the treatment of the cutaneous lesions and proper diet are of importance. The convalescence is of long duration, but as a rule it is without complications. The author concludes that the disease seems to be caused by a benign lesion of the reticuloendothelial system. Antibiotics are of no value.

Cancer of Lung.—According to Alvarez, an early diagnosis of cancer of the lung can be made for the purpose of resection of the tumor. He carried out successful resection in 47 patients with an early diagnosis. The earliest syndrome of the disease is the bronchial syndrome, either catarrhal or hemoptoic and a rheumatoid syndrome of the type of Bamberger-Marie. The bronchial syndrome appeared in 24 out of the total number of 47 patients, whereas the rheumatoid syndrome appeared in 12. The rheumatoid syndrome appeared earlier than the bronchial and when associated with a roentgen tumor shadow in the lung was diagnostic in 90 per cent of the cases. The author advises in patients with any of the mentioned syndromes to verify the diagnosis by: (1) roentgen examination of the chest in the frontal and lateral views and (2) by biopsy obtained by bron-

choscopy. Before the operation the differential diagnosis between cancer and chronic suppuration of the lung is made by the administration of antibiotics. Cancer of the lung and infiltrative types of pulmonary tuberculosis are differentiated by inoculation of guinea pigs with material obtained by bronchial aspiration. In pulmonary hydatidosis and pulmonary mycosis the operation is indicated. The diagnosis is made during the operation. Cancer of the lung is curable by early surgical intervention. The operation is contraindicated: (1) in certain types of hyperacute early course, (2) in presence of local or remote metastases, (3) in heart disease with decompensation and (4) in cachexia in extremely old patients. Infected cancer can be rendered operable by administration of antibiotics.

Schweizerische medizinische Wochenschrift, Basel

78:1213-1236 (Dec. 18) 1948

- Pharmacology of Para-Aminosalicylic Acid; Demonstration, Distribution in the Organism and Renal Elimination. L. Ragaz.—p. 1213.
*Chemotherapy of Tuberculosis with Para-Aminosalicylic Acid. H. Steinlin and E. Wilhelmi.—p. 1219.

Effect of Inhalation Narcosis on Inactivation of Thrombin. L. A. Pálos.—p. 1230.

Para-Aminosalicylic Acid in Tuberculosis.—Steinlin and Wilhelmi treated 103 tuberculous patients with para-aminosalicylic acid. Fifty of these patients were given the sodium salt of para-aminosalicylic acid by mouth, 10 dragées (3 Gm. free acid) four times daily, with a total daily dose of 12 Gm. free acid. Twenty-four of the 50 patients were treated with para-aminosalicylic acid exclusively and 26 were given in addition 0.5 Gm. of streptomycin twice a day, with a total dose of 100 Gm. of streptomycin. Fifty-three patients, 47 of them with pleural empyema and exudate, were treated locally with a 10 per cent solution of para-aminosalicylic acid in isotonic solution of sodium chloride or distilled water. Sixteen of these 53 patients were given dragées simultaneously. In a large percentage of the patients temperature, blood sedimentation rate, cough, expectoration and presence of bacilli in the sputum were influenced favorably. Still more regular and more intensive was the effect of the drug on the general condition, appetite, body weight and hemoglobin content of blood. Thus collapse treatment and other necessary surgical interventions could be carried out which were not feasible before. Treatment with para-aminosalicylic acid was continued for four to six months. The exudate subsided and small cavities disappeared. In several patients with severe pulmonary tuberculosis whose reactions had been positive for a long time, the sputum became negative and a no longer expected phase of recovery was induced by para-aminosalicylic acid alone. The effect of the drug seems to be more beneficial when combined with streptomycin. The tolerance of the para-aminosalicylic acid was in general satisfactory; toxic phenomena did not occur. The local treatment with para-aminosalicylic acid was highly effective in tuberculous exudates and empyemas. The local treatment of cavities and fistulas offers a favorable prognosis provided that an appropriate technic is employed.

Intraperitoneal Penicillin and Adhesions.—Von Rütte injected 30,000 units of penicillin into the peritoneal cavity and 20,000 units of penicillin into the abdominal wall of a woman aged 40 in whom the uterine cavity was opened during the removal of a submucosal myoma. Extensive adhesions between intestine and omentum, and between uterus and intestine, were observed two weeks later when a total hysterectomy was performed because of sarcomatous degeneration of the removed myomatous node. Laboratory experiments on guinea pigs revealed that injections of purified crystalline penicillin produce anaphylactic signs of irritation in the animals. Adhesions were not produced by intraperitoneal administration of high doses of penicillin (50,000 units) in guinea pigs, mice and rats. It is suggested that the case of the woman reported may be one of a rare hypersensitivity of the sarcomatous, injured tissue to penicillin, resulting in adhesions and delayed wound healing. Similar cases have not been observed. Additional evidence is required to confirm the possibility of the occurrence of adhesions in tissues in which changes have occurred.

Book Notices

The Physiology of the Eye. By Hugh Davson, D.Sc., Honorary Research Associate, University College, London. With a foreword by Sir Stewart Duke-Elder, K.C.V.O., M.A., M.D. Cloth. Price, \$7.50. Pp. 451, with 301 illustrations. The Blakiston Company, Division of Doubleday Company Inc., 1012 Walnut St., Philadelphia 5; Toronto 2, Canada, 1949.

This treatise is designed especially for students, opticians and general practitioners who desire an introduction to or a quick reference to physiology of the human eye. It is written in clear style, and subjects of considerable complexity are discussed in a manner that makes them comparatively simple to understand. Exhaustive research in published textbooks and current literature on the part of the author has made it possible for him to choose the important and significant phases of physiology and to present them with reservations rather than to leave the selection to the uninitiated and inexperienced to attempt to obtain a clear understanding of problems that are still the subject of incompatible theories. The drawings are all clearly made and clearly explained so as to avoid confusion. The optical properties of the eye are described according to the best accepted explanations of visual function and ocular motility.

The contents are divided into five sections. The sections on mechanism of vision and muscular mechanics are comprehensive but condensed. The volume contains 435 pages of text. There is an addendum of key references for the convenience of those who wish to carry special investigations to a further extent than this volume permits. The author supports the Young-Helmholtz theory of color vision as a generalization and through references to current studies indicates his preference for this theory over others since proposed and no more provable. The volume well fulfils its purpose and will be a welcome addition to the list of new books available to students.

Diseases of the Nose, Throat and Ear. By William Lincoln Ballenger, M.D., F.A.C.S., and Howard Charles Ballenger, M.D., F.A.C.S., Associate Professor and Acting Chairman of the Department of Otolaryngology, Northwestern University School of Medicine, Chicago. Assisted by John Jacob Ballenger, B.S., M.D. Ninth edition. Cloth. Price, \$12.50. Pp. 993, with 613 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1947.

The appearance of the ninth edition of this work is evidence of its continuing value. As always, this text remains well and profusely illustrated. The concern of the authors for a necessary knowledge on the part of the reader of the anatomy, physiology and pathology of the diseases in the areas involved is obvious from the large amount of space allotted to their discussion. There is a whole new and ably illustrated portion on rhinoplasty. There appears, as well, for the first time, a chapter of considerable value on the headaches and neuralgias of the face and neck region. Several chapters which have long been considered unusually complete and authoritative have been brought up to date. These concern themselves with peroral endoscopy and those portions relating to the physiology and the testing of the inner ear labyrinth as well as its inflammatory diseases. This textbook remains a valuable guide to the diseases of the ear, nose and throat.

The Normal and Pathological Physiology of Pregnancy. Proceedings of the Conference of the Committee on Human Reproduction of the National Research Council, on Behalf of the National Committee on Maternal Health, held in New York City, January 1948. Reprinted from *Obstetrical & Gynecological Survey*, Vol. III, No. 5, October, 1948. Cloth. Price, \$2.75. Pp. 176, with illustrations. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1948.

This book contains fourteen articles read at a conference sponsored by the Committee on Human Reproduction in New York City Jan. 30-31, 1948. The general subject under discussion was "The Normal and Pathological Physiology of Pregnancy," and the fourteen papers read were as follows: "Some Functional Activities of Trophoblast," by George B. Wislocki, Edward W. Dempsey and Don Wayne Fawcett; "Placental Dysfunction in Eclamptogenic Toxemias," by Ernest W. Page; "Patterns of Uterine Contractions in Women During Pregnancy," by S. R. M. Reynolds, L. M. Hellman and P. Bruns; "Pregnancy and the Thyroid Gland," by John

P. Peters, Evelyn B. Man and Martin Heinemann; "The Excretion of Various Hormone Metabolites in Normal Pregnancy," by Eleanor Venning; "Urinary Excretion of Ketosteroids in Pregnancy," by Konrad Dobriner, Seymour Liberman, C. P. Rhoads and Howard C. Taylor Jr.; "Endocrine Patterns in Abortion," by Eleanor Delfs and G. E. Seegar Jones; "Experimental Studies on Nutrition in Pregnancy," by Josef Warkany; "The Biochemical Assessment of Nutritional Status During Pregnancy," by William J. Darby, Richard O. Cannon and Margaret M. Kaser; "Nutritional Needs in Pregnancy in Relation to Nutritional Intakes as Shown by Dietary Histories," by Bertha S. Burke; "Diet Studies in Pregnant Patients," by W. J. Dieckmann and others; "Hemorrhagic Tendencies in Toxemia of Pregnancy" (Practical Evaluation and Management), by Foster S. Kellogg; "Liver Function in Pregnancy," by Equinn W. Munnell, and "The Clinical Management of the Late Toxemias of Pregnancy," by S. A. Cosgrove and Leon C. Chesley.

This book deserves careful study because it contains a great deal of valuable information, it is distinctly authoritative and it reveals what important strides are being made in the problems of human reproduction. All of the articles are important presentations. The book should be in the hands of every one interested in human reproduction and maternal health.

The Management of Binocular Imbalance. By Emanuel Krinsky, M.D., Adjunct Professor of Ophthalmology, New York Polytechnic Medical School, Brooklyn. Cloth. Price, \$12.50. Pp. 464, with 200 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1948.

American Ophthalmology is justly proud of its progress in the study of correction of ocular muscle imbalance. There have recently appeared a number of splendid books by our authors which have presented this complex subject from two points of view, the objective anatomic evidence and measurement (Duane, White and others) and the neuromuscular concept (Lancaster, Adler, Cogan and others) and approach. Dr. Krinsky's well written and illustrated book is a worthy addition to this growing shelf of fine books by American authors. He very ably coordinates the two schools of approach and points out that neither one entirely satisfies the requirements in all cases.

He has resurrected the corneal light reflex of Hirschberg, Priestley-Smith and others, from the limbo of neglected tests for ocular muscle imbalance and by combining it with prism measurements of its displacement in squint has developed a rapid and accurate method of measurement of the angle of squint and the obtaining of useful clinical data, for example in the determination of abnormal retinal correspondence. The reflex prism test will be widely used. The book gives evidence of profound thought, study and originality. It is not easy reading but repays careful attention.

Maladie de famine: Recherches cliniques sur la famine exécutées dans le ghetto de Varsovie en 1942. Redacteur en chef: Dr. med. Emil Apfelbaum. Paper. Pp. 264, with illustrations. Warsaw; American Jewish Joint Distribution Committee, Inc., Suite 800, 270 Madison Ave., New York 16, 1946.

This is a terrible and inspiring document, the account, largely posthumous, of the studies made in the Warsaw Ghetto by the physicians and scientists who set about to gain scientific knowledge from their own extermination by the Nazis. Behind the barricades of the Ghetto 43,000 persons died of starvation in a year, but the experiment was terminated by the technical improvement of the gas chambers, which accounted for 250,000 persons in two months. Some few escaped to carry away the manuscript notes which are here presented as the matter of fact records of clinical observations, controlled experiments and autopsy findings, the latter numbering 3,658 cases of famine death.

Most of the results are presented in verbal descriptions and generalizations with a minimum of numerical data or detailed case histories and almost a complete absence of statistical analysis. The lack of details about methods is also a serious fault, as is the fact that the authors were apparently almost totally unacquainted with the world literature on starvation and nutrition. In spite of such defects, the book is of great value in presenting, for the first time, the picture of active and pro-

gressive starvation in a whole population. The emphasis is on pathologic changes and symptoms, but there were many controlled experiments and measurements on groups selected to represent "pure" uncomplicated starvation. The disappearance of reactivity to epinephrine, to insulin and to tuberculin tests was striking. There are only few data on the incidence and course of concomitant disease, but several features are notable. Infectious disease was, with the exception of typhus and tuberculosis, unimportant, and some diseases, like measles, ran an exceptionally mild course. Rheumatic fever virtually disappeared. As elsewhere in starving areas of Europe in World War II, the manifestations of vitamin deficiencies were remarkable for their absence. There is no information about psychiatric or psychologic problems, though studies on these questions should have been most instructive.

One must believe that the original materials from which the present book was written contain more than here shown. The whole would seem to merit a fuller presentation, perhaps in English and with the benefit of more systematic editing, but even in the present form the book can be recommended to a large audience.

Index to the Literature of Experimental Cancer Research 1900-1935. Prepared by Donner Foundation, Incorporated (originally International Cancer Research Foundation), Philadelphia, Pa. Cloth. Pp. 1057. Donner Foundation, Inc., 2136 Land Title Building, Broad & Sansom Sts., Philadelphia 10, 1948.

This volume is a compilation of all articles bearing on experimental cancer research published between the years 1900 and 1935. The compilers state that the importance or significance of the papers included was not considered and that the bibliography, therefore, is in no way a critical one. A separate author index with complete bibliographic reference is included. The subject index is published separately with excellent selection of detailed subject headings and with many helpful cross references. The publication of this volume is timely; it will be an important tool to the cancer research worker.

Die Durchleuchtungstechnik der Thoraxorgane. Von E. A. Zimmer, Privatdozent an der Universität Basel, Basel, Switzerland. Second edition. Cloth. Price, 12.50 Swiss francs. Pp. 119, with 67 illustrations. Benno Schwabe, Klosterberg 27, Basel 10; imported by Grune & Stratton, Inc., 381 4th Ave., New York 16, 1949.

The second edition, like the first, is a small handbook of a little over 100 pages, intended to serve as a guide in fluoroscopy of the chest. Descriptions are included of the technical apparatus and roentgenoscopic methods and findings. Detailed instruction is offered concerning protection against electrical and irradiation dangers for the patient and the physician; the necessary preparation of the eyes, and the findings, normal and pathologic, in fluoroscopy of the thoracic organs.

The Hospital Purchasing File. Established 1919 as the Hospital Yearbook by the Modern Hospital Publishing Co., Inc. Twenty-sixth edition, 1948-1949. Boards. No pagination. Purchasing Files, Inc., 919 North Michigan Ave., Chicago 11, 1948.

The present volume on hospital products and purchasing follows the pattern of previous editions. As in former years, the book contains a vast amount of information including a classified list of hospital products, an alphabetic list of manufacturers and distributors and sixteen groups of manufacturers' catalogs arranged on a departmental basis with further subdivision into types of products. The catalogs concern the hospital administrative departments, dietary services, housekeeping, laundry, building construction and maintenance, plant operations, professional equipment and facilities relating to surgery, obstetrics, hospital nurseries, anesthesia, oxygen therapy, roentgenologic and laboratory services, hospital pharmacy and physical and occupational therapy.

Planning and reference data are also presented which include check lists for 50, 100 and 200 bed general hospitals, with directions for the planning of x-ray and laboratory departments, rehabilitation facilities, dietary functions, ward and private services, surgical department and housing and educational facilities for nurses. For convenience of reference there are additional lists of hospital associations and federal and other national agencies serving the hospital and allied fields. There has also

been added in this present issue a valuable index of the editorial reference material published in previous editions from 1940 to 1948.

All of this material, which has been carefully compiled and well organized, will be welcomed by hospital administrators and other personnel concerned with the construction, operation and maintenance of hospital services.

Chemical Analysis: A Series of Monographs on Analytical Chemistry and Its Applications. Editors: Beverly L. Clarke and I. M. Kolthoff. Volume V: Aquametry: Application of the Karl Fischer Reagent to Quantitative Analyses Involving Water. By John Mitchell, Jr., M.S., and Donald Milton Smith, Ph.D. Cloth. Price, \$8. Pp. 444, with 51 illustrations. Interscience Publishers, Inc., 215 Fourth Ave., New York 3, 1948.

The authors have performed a valuable service to analytical chemistry by combining in a single volume a large portion of the information available in the literature and at the author's laboratory on the application of the Karl Fischer reagent to quantitative analyses involving water. The Karl Fischer reagent is a solution of iodine, pyridine and sulfur dioxide in methanol. It is the basis of one of the most rapid titrimetric procedures available for the determination of any quantity of water in organic and inorganic materials.

Part I of the book considers the determination of water in various organic and inorganic materials. The method is especially valuable when the system contains nonaqueous volatile components or when a component decomposes on heating.

Part II deals with the quantitative determination of organic functional groups which can enter into reactions involving the liberation or consumption of water. The following is a partial list of such functional groups: alcoholic hydroxyl, carboxyl, acid anhydride, carbonyl, amino, nitrile, ester and peroxide.

The text provides sufficient detail to permit laboratory determinations without further references. An excellent index is provided. This book is recommended as a valuable addition to any medical or biologic chemistry library.

La Marihuana en la America Latina: La Amenaza Que Constituye. Por Pablo Osvaldo Wolff, Doctor en medicina y filosofia. Paper. Pp. 55. Libreria y editorial "El Ateneo," Florida 340—Córdoba 2099, Buenos Aires, 1948.

The title "La Marihuana en la America Latina" does not do justice to the wide scope of this monograph. While Dr. Wolff has placed particular emphasis on Latin American aspects, his discussion is of general application and interest. He has made a painstaking review of information on the abuse of cannabis. It is a much needed compilation of current knowledge in one volume. The author has done his usual erudite, well documented job. The style is interesting, and the book is recommended to readers desiring a comprehensive and accurate view of this field. The bibliography is extensive. An English translation is being printed.

Manual of Public Health Hygiene. By J. R. Currie, M.A., M.D., LL.D., County Medical Officer of Buteshire and Medical Officer of Health of the Royal Burgh of Rothesay, and A. G. Mearns, M.D., B.Sc., D.P.H. Third edition. Cloth. Price, \$9. Pp. 724, with 216 illustrations. Williams & Wilkins, Mt. Royal & Guilford Aves., Baltimore 2, 1948.

In this third edition of the well known textbook 122 new figures and 32 new tables have been added by the authors, who have produced a thoroughly revised and comprehensive volume. New sections include health education and medical climatology. Discussion and proposed use of fumigation receive more emphasis than given in some texts in the United States. In general, the information presented is sound.

From a concluding section entitled The Social Vista, the following passage deserves quotation to illustrate the constructive approach:

"The complex problem of the aged will be solved only when the geriatrist, the economist, the almoner, the health visitor and the social worker cooperate, under central direction, to encompass the difficulties which beset the later years. By whatever means they are to be achieved, the aims are clear. They are the fullest possible restoration to health and happiness of those whose days of service are over; and the provision for them of an environment in which physical comfort and mental tranquillity combine to give in their lives peace at eventide."

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

BREAST FEEDING DURING PREGNANCY

To the Editor:—What is the effect on mother and baby if the baby is nursing and the mother becomes pregnant? Has work been done to explain the altered physiology?

M. K. Braly, M.D., Mooreland, Okla.

ANSWER.—The English literature does not help much in appraising the value of milk from pregnant mothers. Finkelstein stated that pregnancy upsets the breast-fed infant. Holt and McIntosh stated that milk from a toxemic patient may be toxic to the infant. Sedgwick stated that clinical evidence did not indicate that such milk was harmful. Mitchell and Nelson were of the opinion that after the first month of pregnancy breast milk was contraindicated. None of these opinions were substantiated with adequate scientific data. However, three articles in the Japanese literature reported an infant disease called "atomitsuware," apparently associated with breast feeding from pregnant mothers.

Arakawa devised a test which indicates the amount of peroxidase in milk. The absence of this substance (negative Arakawa) is found to be associated with the following: (1) nutritional disturbances of infants, (2) all milk from pregnant mothers and (3) diseases of infants of unknown relationship to breast feeding during pregnancy. Infants who were fed milk which lacked peroxidase (negative Arakawa) showed symptoms of dyspepsia, anemia, thrombocytosis and large platelets, findings which became more pronounced with the continued use of negative milks. After the administration of vitamin B for a long period the mother's milk became less toxic and the baby's platelets became normal. However, in some instances the babies became so ill that weaning from the breast was imperative.

The onset of pregnancy in a lactating woman is not an immediate indication for weaning from the breast. The baby should be watched closely, and, if any of the symptoms mentioned develop, the infant should then be changed to artificial feeding.

THERAPEUTIC LIPIODOL®

To the Editor:—Lipiodol® is used for roentgenographic visualization of hollow viscera and sinuses. I have seen it used frequently in the treatment of bronchial asthma and bronchitis. Do harmful effects occur following the frequent instillation of lipiodol® into the trachea and bronchi? Does it cause pneumonitis?

M.D., North Carolina.

ANSWER.—Instillations of iodized oil, chiefly lipiodol®, are used for both diagnosis and treatment. They are essential in confirming the diagnosis of bronchiectasis, as they reveal the condition of the bronchial tree more clearly and thoroughly than any other method of examination, including bronchoscopy.

Therapeutically, the procedure has stirred up a storm of criticism. Lipiodol® is an iodized poppyseed oil containing 40 per cent iodine in organic combination. Lipiodine®, the ethyl ester of diiodobrassic acid, contains 41 per cent iodine. These substances are usually coughed up quickly, or they may be slowly absorbed. Occasionally, they may remain in the lungs for long periods. Flamm reported retention in 2 cases for one and two years, respectively, with continued severe asthma, which the author believed due to areas of pneumonitis around the residual oil; 1 of these patients also had symptoms of iodism.

The therapeutic use of iodized oil followed the observation that in some asthmatic patients improvement occurred after the diagnostic instillation of lipiodol®. The iodine in the oil probably does not act as an antiseptic, but the oil is heavier than sputum and is, therefore, supposed to displace the sputum from the lowest air passages, so that expectoration is facilitated. The lubrication of inspissated mucous plugs may also be a factor.

The earlier reports were rather enthusiastic. Anderson reported "complete relief" for one to eight years in 90 per cent of 200 cases of asthma in which the average duration was twelve years; failure occurred in only 20 cases (10 per cent). Later reports were more conservative, and workers have once again urged that the procedure cannot hope to obtain the good results which can usually be secured by correct allergy surveys, followed by specific avoidance, with or without hyposensitization. Moore treated asthmatic patients who had not been aided by the usual allergy regimen. He instilled iodized oil one hundred

and eighty-nine times in 35 patients: 3 were made worse (8.5 per cent); 13 unimproved (37.2 per cent); 10 improved (28.6 per cent), and 9 had good results (25.5 per cent). In 1 patient acute iodism developed.

Replies to a questionnaire sent to sixty-four doctors were as follows: About one third of the doctors were still using the oil, but only in a few selected cases; in 267 cases of bronchial asthma, failure occurred in 73.4 per cent, improvement in 24.7 per cent, and "cure" in 1.9 per cent. In 39 cases of asthmatic bronchitis, failure occurred in 76.4 per cent, improvement in 22.8 per cent, and "cure" in 0.8 per cent. Most workers were either opposed to the method or apathetic. Crip and Hampsey also noted untoward reactions due to idiosyncrasy to iodine or poppyseed, circulatory failure, spread of infection or pulmonary damage. Fatalities can occur, and they conclude that the procedure can only bring temporary relief in a small percentage and that it is not without danger.

In summary, good results can be obtained in some cases, and untoward reactions can be minimized by observing proper precautions and by the preliminary administration of the oil to test for sensitivity to iodine or poppyseed oil. The procedure, if used at all, should be limited to asthmatic patients, with or without associated bronchiectasis, who have not responded to the usual antiallergy regimen. One should add that severe reactions, sometimes fatal, have occurred from the use of cocaine or one of its derivatives during the procedure, especially if the procedure is carried out bronchoscopically.

FAMILIAL BOWING OF LEGS

To the Editor:—What is the correct procedure to follow in the case of a 5 month old infant girl whose legs show definite bowing? She was delivered normally, is otherwise healthy and has had antirachitic medication from birth. Her father, paternal aunt, grandfather and grandmother also have definite to moderate bowing of the legs, all of the same pattern—that is, the bowing is entirely in the legs and the point of maximum bend is at the junction of the upper and middle thirds of the leg. Her father and aunt definitely received cod liver oil in infancy and do not show signs of previous rickets. Is this an inherited feature? What can be done, besides osteotomy, to influence or correct the bowing so that the girl will have straight legs later? If indicated, when is osteotomy best performed?

M.D., New York.

ANSWER.—The bowing of the legs in the 5 month old infant girl whose father, aunt, grandfather and grandmother show similar bowing is probably a familial condition and due to inheritance. The bowing due to rickets usually is not manifested until the infant or child stands, and is accompanied by craniotabes, enlarged fossae of the skull, large wrists and ankles, rachitic rosary with Harrison's groove and delayed closure of the fontanelles. The laboratory findings in rickets include changes in the epiphyses in the roentgenogram and a lowering of the plasma phosphorus. The blood phosphatase is usually high in active rickets.

Besides osteotomy to influence or correct the bowing, gentle corrective manipulation and the discouragement of weight bearing may be effective. Braces are usually ineffective.

If the bowing is extreme osteotomy will be necessary, and had best be done between the ages of 3 and 6 years. Alfred Hess has described a group of infants with nonrachitic soft bones, a number of whom also had bowed legs (*Am. J. Dis. Child.* 41:1309-1316 [June] 1931).

SUDDEN DEATH IN INFANCY

To the Editor:—A 17 month old girl suddenly became unconscious while being dried after her morning bath. She had been completely normal until six weeks before, when there was a great increase of body weight and spontaneous growth of pubic hair. The week previously she had been placed on 1/10 grain (6 mg.) thyroid three times a day. While being examined the baby went into a convulsive seizure; despite all methods of therapy, her abdomen became distended and temperature rose from normal to above 108 F. within one hour. She died suddenly. Permission for necropsy was not obtained. The condition appeared to be a cerebral disorder, probably pituitary or perhaps adrenal. What are the other possibilities of diagnosis and causes of death?

M.D., New York.

ANSWER.—The cause for the sudden death in this seventeen month old infant with terminal hyperpyrexia (108 F.) was probably of cerebral origin. The sparsity of clinical history and findings make the suggestions for the diagnosis and causes of death difficult. In addition to tumor of the pituitary or adrenal gland, one might suggest, as other causes of sudden death, brain tumor, brain abscess, ruptured aneurysm of cerebral origin, acute hemorrhagic encephalitis or acute septic infection.

The evidence of early growth of pubic hair need not have been directly associated with the sudden death. The fact that the child died in convulsions and with hyperpyrexia makes one think of a cerebral infection in the region of heat-regulatory center.

CHOLINE IN ATHEROSCLEROSIS

To the Editor:—1. What is the present status of choline relative to its use in coronary thrombosis and the associated atherosclerotic diseases? 2. Are there any reports in literature regarding the use of choline as a preventive measure against atherosclerotic diseases? 3. What is the present concept of the action of choline in these conditions? 4. What are the possible untoward reactions of choline used for long periods? 5. What is the therapeutic dosage?
Ivan Gilbert, M.D., Columbus, Ohio.

ANSWER.—The use of choline in the treatment of coronary atherosclerosis in human beings is in the experimental stages. There have not been detailed reports in the literature on the effectiveness of this substance in the treatment or prevention of atherosclerosis. Hermann (*Texas State J. Med.* 42: 260, 1946) has reported that the serum cholesterol of 35 patients given 3 Gm. of choline daily for one to four months is lowered on the average of 20 per cent. Morrison (*Ann. Heart J.* 36: 466, 1948) has studied the effect of choline on the serum cholesterol of 200 patients with coronary arteriosclerosis for periods up to two years. Deleterious effects were not observed. Choline has been fairly extensively prescribed in doses of 3 to 4 Gm. daily to patients with cirrhosis of the liver without untoward effects. An occasional patient will experience gastrointestinal intolerance to this medication, which subsides promptly on discontinuance.

The rationale for the use of choline in atherosclerosis results from studies in rabbits in which experimental atherosclerosis had been produced by high cholesterol diets. Steiner (*Proc. Soc. Exper. Biol. & Med.* 38: 231, 1938; *Arch. Path.* 45: 327, 1948) and Kesten and Silbowitz (*Proc. Soc. Exper. Biol. & Med.* 19: 71, 1942) have shown that choline is effective in preventing experimental atherosclerosis in cholesterol-fed rabbits for a limited period of time. Steiner (*Proc. Soc. Exper. Biol. & Med.* 38: 411, 1938) has also reported that choline causes reabsorption of previously induced atherosclerosis in rabbits. Hermann (*Proc. Soc. Exper. Biol. & Med.* 61: 302, 1946) has found that choline reduces the level of cholesterol and cholesterol esters in the serum, the aorta, heart muscle and the liver of old hens.

GASTRIC CRISIS IN SYPHILIS

To the Editor:—In 1919 a patient contracted syphilis for which he refused to take adequate treatment. In 1947 gastric crises developed, occurring about every sixty days. During these episodes, which occur every few days now, he requires morphine to relieve the gastric pain and vomiting, which will continue for days unless so treated. He has had a positive blood Wassermann reaction at all times. The spinal fluid is Wassermann negative at all times. He has been confined in three government hospitals for treatment during the last two years, as he is a veteran, and has received 13,500,000 units of penicillin with apparent relief for a few days. The staffs of the hospitals do not give encouragement to this man. A sympathectomy has been advised, but a neurologist of Vanderbilt University disagrees with this suggestion. Can you offer some suggestions that will be of advantage to this man?
G. P. Zirkle, M.D., Kingston, Tenn.

ANSWER.—Additional information regarding spinal fluid findings is necessary to evaluate the present status of this patient's central nervous system involvement. This should include a cell count and determination of total protein and colloidal gold reactions, in addition to a properly performed quantitative complement fixation test. If the cell count and total protein are within normal limits it may be assumed that this patient has an inactive (Dattner-Thomas) type of spinal fluid, indicating an arrested syphilitic process. In such circumstances, further antisyphilitic therapy is not indicated. The inquirer is referred to the textbook "Modern Treatment of Syphilis," second edition, by J. E. Moore (Springfield, Ill., Charles C Thomas, Publisher, 1941), pages 435-438, for detailed information regarding the symptomatic and surgical treatment of tabetic crises. Surgical procedures should be used only as a last resort.

If the spinal fluid findings indicate an active syphilitic process (elevated cell count and total protein) additional therapy is indicated and may afford relief of his symptoms.

HORMONE CREAMS

To the Editor:—Of what value are creams or ointments containing estrogenic hormones in causing breast enlargement? Will these ointments cause breast enlargement by actual growth of breast tissue? What are the contraindications to use of such ointments? Several such ointments are manufactured by pharmaceutical houses which claim good results in their advertising literature.
M.D., Washington, D. C.

ANSWER.—Ointments, creams or tinctures of estrogens are effective in causing stimulation of growth of the accessory sex organs on local application under the proper conditions. When applied to the breasts, they will cause enlargement of this organ through growth of the breast tissue, which, however, recedes in size with cessation of estrogen application. Breast enlargement, however, will take place only where there is a potentiality of growth. In women who menstruate regularly, but whose breasts are small, the addition of ointments or creams containing

estrogen will be ineffectual, since they already have received adequate stimulation. In a woman with ovarian failure, however, such an application of hormone should cause an enlargement of the breasts as long as the material is applied. The contraindications to this type of therapy are those for estrogens in general. If estrogens are applied to a woman who is menstruating regularly, her cycles may be deranged through suppression of the anterior pituitary by the estrogen.

INCUBATION TIME OF HEPATITIS

To the Editor:—Could blood plasma or serum given in April 1947 be responsible for homologous serum hepatitis occurring in June or November of the same year? Could blood given in July be responsible for homologous serum hepatitis occurring in November?

J. S. Collins, M.D., Wabasha, Minn.

ANSWER.—Two similar types of jaundice may be transmitted by transfusion of blood or plasma. One of these, infectious hepatitis, ordinarily has an incubation period of twenty to forty days. The other, homologous serum jaundice (serum hepatitis), ordinarily has an incubation period of sixty to one hundred and forty days.

VITAMIN E AND BLOOD CHOLESTEROL

To the Editor:—Does vitamin E have any influence on blood cholesterol? A drug salesman told me he had had effort angina for a long time until he began taking it. Now he can walk up a long hill rapidly.

M.D., New York.

ANSWER.—Information on this subject is not available from human subjects, but when rabbits and rats are deprived of vitamin E, the cholesterol content of muscle is significantly increased. A similar increase was found in brain and nervous tissue of rats, and a hypercholesterolemia was reported in rabbits.

Data are not available on the relation between blood cholesterol and effort angina. Heart muscle is normally rich in vitamin E. When rats are deprived of vitamin E, blood pressure is lowered.

CIRCUMCISION

To the Editor:—Exception can be taken to the answer given on circumcision on page 273 of The Journal, January 22, which read in part: "It is generally conceded that routine circumcision of the newborn is definitely indicated."

True, many physicians practice routine circumcision. By contrast, a number of obstetricians do not subscribe to this procedure. At the Chicago Lying-in Hospital, our practice is to allow circumcision on the indication that the prepuce cannot be freed and retracted. Then it is only done on normal full term infants who are healthy and gaining weight. Circumcision is, as a rule, without complication, but serious results have occurred on any service where a sufficient number have been performed. These hazards include hemorrhage, which can be severe and potentially fatal, infection, which may be virulent, and, finally, deforming scars have resulted which have caused much alarm to the parents and to the child as he grew up. For these reasons, the procedure for the staff cases at the Chicago Lying-in Hospital is as follows:

Circumcision is not done if the prepuce can be retracted. (The mother is instructed in the care of the baby.) It is not done on premature babies, or those not gaining weight or afflicted with a blood disease, with an infection or otherwise abnormal. For babies suffering from one of these complications, when there is an indication for circumcision, it may be done after the baby has completely recovered.

Occasional circumcision is done because of insistence of the parents, but only after a fair discussion of the risks involved. Ritual circumcisions are performed on the eighth day, or later if the infant's condition is not favorable at that time.

H. Close Hesseltine, M.D., Chicago.

IMPOTENCE IN DIABETES

To the Editor:—In The Journal, January 29, page 345, a questioner asks about treatment of impotence in diabetes. The consultant set forth some interesting theories, and advises the use of testosterone propionate. He then adds that it has not proved to be of help in many cases of impotence.

We have recently reported some work in this regard. (The Inactivation of Estrogens by Lipotropic Substances—Studies of Liver Dysfunction, *Rev. Gastroenterol.* 15: 762 [Oct.] 1948. We were treating certain cases of diabetes with choline on the assumption first enunciated by Soskin, and Biskind and Schreier, that certain cases of diabetes in older persons were improved when their hepatic function was improved. In addition to improvement in carbohydrate function these patients reported that libido was also improved. It seems unlikely that this improvement in the carbohydrate tolerance and in libido would be on a psychogenic basis. We think we have proof that such was not the case. Our theory on the action of choline in this regard is that with better hepatic function better inactivation of estrogen occurs in the patient. It is well known that the male has both estrogen and androgen in his body. With subnormal inactivation of estrogen, it may accumulate in the body and antagonize the androgen and in this way cause loss of libido.

Giving testosterone would have only a temporary effect, since it depresses the patient's own testicular secretion. It would therefore seem to be contraindicated in a 37 year old person unless there is absolute evidence of testicular atrophy.

PATHOGENESIS, DIAGNOSIS AND TREATMENT OF HUMAN TOXOPLASMOSIS

J. K. FRENKEL, M.D.
Hamilton, Mont.

Toxoplasmosis is an infection occurring in nature. In animals it has been observed in an acute stage¹ and in a chronic latent stage.² In human beings the following clinical forms have been recognized, characterized chiefly by (1) congenital or neonatal meningo-encephalitis, usually associated with hydrocephaly, chorioretinitis, cerebral calcifications and convulsions; (2) atypical encephalitis; (3) postencephalitic sequelae, or (4) pneumonitis associated with fever and a rash. Subclinical forms of the infection have been diagnosed from the presence of specific *Toxoplasma*-neutralizing antibodies in certain persons and from the delivery of toxoplasmic infants by seemingly healthy mothers.³ I recently had the opportunity to study pathologically 5 cases of fatal congenital toxoplasmosis in 2 of which clinical diagnosis had been made and *Toxoplasma* isolated. The lesions produced by three strains of *Toxoplasma* were studied in experimental animals. In addition, about 80 patients with uveitis and more than 200 other patients were investigated clinically, serologically and by cutaneous test for evidence of past or present infection with *Toxoplasma*. The detailed results of these investigations are to be published elsewhere.⁴ The purpose of this paper is to describe and to reinterpret the pathogenesis of the infection which will serve to facilitate diagnosis of the disease and which may form a rationale for its treatment.

HISTORICAL INTRODUCTION

Toxoplasma gondii, the type species, was first described by Nicolle and Manceaux⁵ from the Institute Pasteur in Tunis in the year 1908. The name is derived from the Greek *toxos*, meaning a bow or arc,

connoting the lunate shape of the organism (fig. 1A and B). The specific name *gondii* is derived from the name of the type host, the *gondi* (*Ctenodactylus gondi*, Pallas, 1778), a small North African rodent, which was used as a laboratory animal at the Institute Pasteur. The organism is generally believed to be a protozoan. Reproduction is by multiple binary fission. Proliferating organisms and pseudocysts may be distinguished. In the same year (1908) Splendore⁶ described the organism isolated from a rabbit in Brazil. Jankú,⁷ in 1923, described the first well authenticated case in a human being from Czechoslovakia. It was that of an infant with unilateral microphthalmus and bilateral chorioretinitis. In 1929, Levaditi and his co-workers⁸ published an extensive experimental study of *Toxoplasma* isolated from rabbits. Sabin and Olitsky⁹ were the first to prove the existence of the organism in North America (1937), when they encountered *Toxoplasma* in a guinea pig. These authors also demonstrated the development of neutralizing antibodies in the course of the disease in Rhesus monkeys. Likewise in 1937, Wolf and Cowen¹⁰ reported the first instance of human infection with *Toxoplasma* in the United States. Subsequently, these authors, together with Paige, described 10 further cases in infants and children.^{3a} Pinkerton and Weinman,¹¹ in 1940, reported the first fatal case in an adult, a Peruvian with concomitant bartonellosis. In the following year, Pinkerton and Henderson¹² published a study of 2 further fatal adult cases of toxoplasmosis, observed in the St. Louis area. Sabin,¹³ in 1941, described 2 cases in children from Cincinnati characterized by encephalitic symptoms. One of these children survived. Sabin and Warren,¹⁴ in 1942, reported successful treatment of experimental toxoplasmosis with sulfapyridine and sulfathiazole, but ineffectiveness of certain antiprotozoal drugs that were toxic in vitro.¹⁵ The same authors¹⁶

also studied the complement fixation reaction in toxoplasmic infection. Sabin and Ruchman¹⁷ investigated the characteristics of the Toxoplasma-neutralizing antibody in monkeys and human beings.¹⁸ Heidelberg¹⁹ evaluated the Toxoplasma-neutralizing antibody test in patients with chorioretinitis. The ocular lesions of toxo-

been added to these. Infections in both human beings and animals have been reported from all over the world.²⁷

PATHOGENESIS OF TOXOPLASMOSIS

Acute Toxoplasmosis.—The acute infection is a generalized one,²⁸ involving every organ, although lesions may be only microscopic in character. Toxoplasma has been observed to proliferate intracellularly in many types of cells. It is perhaps most frequently found in macrophages, fibroblasts, reticular cells and sinusoidal lining cells, in pulmonary alveolar lining cells, and in smooth muscle and cardiac muscle cells. Smaller or larger areas of necrosis may be associated with Toxoplasma. As a cellular response macrophages and lymphoid cells predominate over amphophilic granulocytes. In the central nervous system both neuronal and microglial elements may contain the organisms, and the microglial nodule is the typical response to injury. Most frequently encountered are: interstitial pneumonitis, myocarditis, encephalitis, splenitis, hepatitis and orchitis. Clinically the pulmonary or meningoencephalic symptoms may be more prominent, and a cutaneous rash, and icterus due to hepatitis, are of frequent occurrence.

The numbers of organisms present, the degree of necrosis and the intensity of the cellular reaction in animals were observed to be variable, depending on the host as well as on the strain of Toxoplasma. Too

degrees of organ involvement. The age of the patient appears to be of importance, since infants show more severe and extensive lesions at autopsy than do adults. It is important to keep in mind that the acute stage of the infection may be relatively or entirely asymptomatic, especially so in adults, and need not cause disease.

Fig. 3.—Microglial nodule in mouse brain. The cells are better outlined since fixation was prompt and more appropriate to the silver technic (formaldehyde ammonium bromide, Hortega's silver carbonate, $\times 162$).

Subacute Toxoplasmosis.—This terminology is used to designate the cases in which there are regressing lesions in the extraneural viscera, whereas in the central nervous system and the eyes *Toxoplasma* continues to proliferate actively. Most of these patients acquired toxoplasmosis antenatally or neonatally, suggesting a low degree of resistance of fetuses and infants to *Toxoplasma*. The majority of neonatal cases of toxoplasmosis fall into this group. Here one sees in extraneural tissue evidence of past acute infection in the form of focal accumulations of lymphocytes, plasma cells and eosinophilic granulocytes. Fibroblasts are proliferating and are organizing areas of necrosis. *Toxoplasma* is not encountered in these foci.

The central nervous system presents a completely different picture. The basic lesion, the microglial nodule, is of common occurrence, and *Toxoplasma* is frequently found associated with it. These microglial nodules have been termed granulomas by most other authors,²⁹ supposedly consisting of accumulations of epithelioid cells and thought to be derived from hyperplastic endothelial and adventitial cells from the vessel walls as well as possibly from large hematogenous mononuclear cells.¹⁰ In my hands, appropriate methods of silver impregnation showed these lesions to be made up of microglial cells in both human and animal material (figs. 2 and 3). These microglial cells are derived from preexisting microglia and from perithelial cells,

but no significant endothelial proliferation was found. Furthermore, the hypertrophic microglia of the nodules present a different appearance from epithelioid cells of a tuberculoma in neural tissue.

The disappearance of *Toxoplasma* from the extra-neural viscera can best be explained on the basis of acquired immunity. Equivocal neutralizing antibody reactions, thought to be due to low titers of antibody, were obtained with the serums of 2 patients³⁰ succumbing with subacute toxoplasmosis. The persistent proliferation of *Toxoplasma* within the central nervous system may be explained by the observed poor diffusion of serum antibody into brain substance. This has previously been observed for bacterial antibody³¹ and viral antibody³² in rabbits where the ratio of serum antibody content versus brain antibody content, versus cerebrospinal fluid antibody content, was approximately equivalent to 300:3:1. It is of interest to note that the serum-cerebrospinal fluid antibody ratio parallels the protein content of the two fluids (6,000:20 mg. per hundred cubic centimeters), thus perhaps explaining this apparent "blood-brain-barrier" on the basis of a differential diffusion gradient for proteins. Differential *Toxoplasma*-neutralizing antibody titers have been

demonstrated in human serum, peritoneal fluid, brain and cerebrospinal fluid.³³

The other characteristic and unique lesion in the central nervous system is the periventricular reaction zone (figs. 4 and 5 *A*). This zone surrounds the lateral and third ventricles, wherever the ependymal epithelium has been denuded. Proceeding from the relatively unchanged brain tissue lumenally, this reaction zone may be conveniently described as consisting of four subzones of (1) cellular infiltration and thrombosis of capillaries, (2) thrombosis of large vessels, (3) cellular necrosis and (4) repair. The first subzone shows much microglial proliferation, necrobiosis of

Fig. 5.—*A*, periventricular reaction zone, with the four subzones (1) of cellular infiltration and thrombosis of capillaries, (2) of thrombosis of large vessels, (3) of cellular necrosis and (4) of repair (phosphotungstic acid hematoxylin $\times$ about 192). *B*, periventricular subzone 2, showing fibrin exudation (black) surrounding a thrombotic vessel (formaldehyde-phosphotungstic acid hematoxylin $\times$ about 300).

astrocytes and neuronal cells, as well as much perivascular lymphocytic and granulocytic infiltration accompanying the damaged capillaries. The second subzone, of vascular thrombosis, is characterized by pronounced perivascular fibrin exudation, mural edema and plasma cell infiltration (fig. 5 *B*). The third subzone is marked by necrosis involving all cells excepting fibroblasts in the walls of certain large vessels. The fourth subzone, of repair, is formed by proliferating fibroblasts and small vessels that are derived from certain large vessels which have not undergone complete thrombosis in the

outer three subzones. Numerous plasma cells and adventitial wandering cells as well as *Toxoplasma*, both viable and degenerating forms, are found here. Calcium salts have been deposited throughout the third periventricular subzone and in bands of degenerating *Toxoplasma* in the fourth one.

The ventricular foramina of Monro and the aqueduct are blocked by inflammatory exudate. The ventricular lumens contain fluid of high protein content (1,000 to 2,600 mg. per hundred cubic centimeters), which cannot escape. *Toxoplasma* is frequently found in this ventricular fluid, which has been shown to contain *Toxoplasma* antigen (v.i.). If one recalls the aforementioned evidence for the presence of *Toxoplasma*-neutralizing antibodies in the serum, the zone of necrotizing vasculitis surrounding the antigen-containing ventricles strongly suggests this zone to be the site of an antigen-antibody reaction.

The necrotizing vascular reaction may be explained by antigen and antibody reacting in the scanty intercellular fluid and on the surface of the mural cells, thereby damaging the latter. Whatever small amount of blood reaches the fourth subzone contains less antibody, since much of it has been neutralized in passage through the outer zones. Furthermore, the proliferating fibroblasts in this fourth zone form a loose type of connective tissue, the interstices of which are filled with much antigen-containing fluid. This allows any remaining serum antibody to be neutralized in a liquid medium and in less contact with cells. The necrotizing vasculitis previously described bears considerable resemblance to the necrotizing allergic reaction, according to Bohrod's³⁴ classification. Ependymal epithelium covering the ventricular walls and the choroid plexus tufts seem to form an effective barrier for the ventricular fluid seepage into the surrounding tissue where it can come into contact with vascular channels containing antibody. Desquamation of a few choroid plexus lining cells gives rise to a formation of fibrinoid collagen in the plexus stroma. In summary, the periventricular reaction zone resembles an antigen-antibody reaction *in vivo*, analogous to a reaction of hypersensitivity. This lesion appears to have no exact parallel in any other infection.

The high protein content of the ventricular fluid (up to 2,600 mg. per hundred cubic centimeters), mentioned previously, is derived in part from the plasma that permeated the damaged vascular walls and in part from necrotic brain tissue that desquamated into the ventricles. The protein level of the subarachnoid fluid is lower, usually between 100 and 600 mg. per hundred cubic centimeters. It is in nearer to normal equilibrium with the blood stream owing to drainage and the vascularity of the meninges.

The clinical signs and symptoms of subacute toxoplasmosis, such as hydrocephaly and convulsions, are readily explained by the lesions described. Cerebral calcifications are usually small or even microscopic and may not be detectable radiologically. Chorioretinitis, however, is the most consistent clinical observation of the neonatal subacute disease, and it has been found in virtually every patient when it was looked for. Both exudative and proliferative types of retinitis and iridocyclitis have been encountered. The choroid usually shows less involvement and more chronic inflammation than the retina. A vitreous exudate is usually associated with the active retinal lesions, thus obscuring

33. Frenkel, J. K.: Unpublished data.

34. Bohrod, M.: Classification of the Histologic Reactions in Allergic Diseases, *Am. J. Med.* 3: 511, 1947.

the latter on fundoscopic examination. *Toxoplasma* organisms are found in the retinal lesions, frequently in the form of pseudocysts.

The subacute retinitis is analogous to the cerebral lesions, the retina being of neuroectodermal derivation. The ocular fluids contain an amount of protein similar to the cerebrospinal fluid (normal range 15 to 30 mg. per hundred cubic centimeters), hence similarly low antibody levels may be assumed to exist in the latter two fluids, as compared with the blood serum. The continued proliferation of *Toxoplasma* in the retina may therefore be analogous to the persistent proliferation of the organisms in the central nervous system. In the latter case, evidence has been presented that it proceeds because of the low level of specific antibodies present in that location.

Symptomatic subacute toxoplasmosis frequently has a fatal outcome, but surviving patients have been observed. Signs and symptoms in the surviving patients are variable, depending on the severity of lesions present. Chorioretinitis again is the most outstanding sign and may cause decided visual impairment if the macular area is involved. Since most of these patients at the time of their observation were in the chronic stage of the disease, they will be presented later.

Chronic Toxoplasmosis.—This terminology is used in reference to cases with clinical or laboratory evidence of toxoplasmosis without signs of widespread activity. Since no reports of autopsy of previously symptomatic patients are available and since *Toxoplasma* has not been isolated from any such cases of chronic disease, the crucial question of whether there is persistence of *Toxoplasma*, hence true chronicity, must remain only partially answered. There is much evidence, however, to favor the hypothesis of a chronic state of toxoplasmic infection in human beings. On several occasions, structures resembling *Toxoplasma* pseudocysts (fig. 1 C and D) have been found in routine autopsy material.³⁵ The recurrence of active chorioretinitis in patients showing the scars of subacute toxoplasmosis can best be explained by the hypothesis of *Toxoplasma* persisting through a latent stage. Finally, chronic latent toxoplasmosis has been demonstrated to occur in mice,³⁶ rats,^{2b} guinea pigs and rabbits³⁷ and hamsters.³³ Certain of these animals were found to have a chronic latent infection which had been acquired in nature, while in others this state has also been demonstrated experimentally. Depending on the virulence of the *Toxoplasma* strain as well as on the degree of host resistance (and hence the duration of the subacute stage of infection), fewer or larger numbers of *Toxoplasma* pseudocysts are found in the central nervous system and the eyes of such animals with chronic latent disease.³³ These pseudocysts may persist for considerable periods, probably for many years. An argyrophilic cyst wall (fig. 1 D) has been demonstrated on them,³³ which is probably the reason that they usually do not evoke a cellular reaction. However, the presence of small foci of necrosis and of microglial proliferation in animals with the chronic disease suggests the possibility of the rupture of such pseudocysts,

with the release of antigenic material in the form of organisms and other proteins. Whereas chronic toxoplasmosis may be clinically and pathologically latent, reactivation may occur secondary to rupture of pseudocysts.

The failure to isolate *Toxoplasma* from the brain of monkeys that have passed through the acute stage of the infection³⁸ and from the brain of an asymptomatic patient who showed, in results of cutaneous and serologic tests, evidence of past toxoplasmic infection³³ might indicate that chronic latent toxoplasmosis may be of rare occurrence in primates. However, these few experiments cannot be regarded as conclusive. The numbers of organisms persisting in the brain of a relatively resistant host may be very small, so that, after grinding, *Toxoplasma* liberated from the protective pseudocyst wall may be inactivated even by the small amount of neutralizing antibody present in the unperfused brain. The brain of the patient just mentioned possessed slightly greater *Toxoplasma*-neutralizing capacity than her cerebrospinal fluid.³³ In contrast, the number of *Toxoplasma* pseudocysts in the central nervous system of rodents may be large enough to be found on routine microscopic brain sections. Their complete neutralization would be of less likely occurrence, because of the quantitative relationships between organisms and antibody.

Clinical signs and symptoms of past or persistent (chronic) toxoplasmosis may be variable according to the amount of damage produced during the acute and subacute stage of the disease. In symptomatic patients, chorioretinitis is the most frequent sign, followed in incidence by electroencephalographic evidence of cerebral damage, cerebral calcifications demonstrable radiologically and other signs, such as microcephaly, hydrocephaly, ocular malformations, spastic paraplegia and their associated symptoms. The significance of toxoplasmosis in the causation of anterior uveitis has not been clearly established. The rupture of a pseudocyst within the retina is suggested as the causative mechanism of recurrent acute chorioretinitis in patients with laboratory evidence of toxoplasmosis. The antigen liberated gives rise to a hypersensitivity reaction, characterized clinically by the exudative and hemorrhagic phenomena of "granulomatous posterior uveitis."³⁹ Since this reaction may persist for a prolonged period of time, it may be assumed, first, that antigen has been released into the retina and vitreum, whence absorption and neutralization would occur relatively slowly, and, secondly, that *Toxoplasma* might proliferate within the retina for some time, again releasing more antigen. As has been mentioned before, *Toxoplasma*-neutralizing antibody levels may be expected to be as low in the ocular fluids as in the cerebrospinal fluid, since the protein content of these two fluids is similar. Of 28 patients with "granulomatous chorioretinitis" studied by me,⁴⁰ 20, or 71 per cent, showed evidence of toxoplasmosis in results of cutaneous and serologic tests. The mean age of these patients when first seen was 23 years; their mean age when symptoms or signs were first noted was 13 years, whereas lesions most likely were

present at a much earlier age in many of them. Fourteen of the 20 patients (70 per cent) were female.

Evidence for the occurrence of asymptomatic (and later chronic?) toxoplasmosis has been accumulated from the serologic observations associated with dermal hypersensitivity to *Toxoplasma* antigen. A survey conducted by me at the University of California Medical School revealed an incidence of 10 per cent in a group of 50 normal persons between the ages of 20 and 35 years and an incidence of 28 per cent in a group of 50 hospital patients between 50 and 83 years of age. None of these patients had any of the recognized clinical signs of toxoplasmosis, and from only 1 was a history of encephalitic symptoms elicited. Whereas the incidence of past (or persistent?) toxoplasmosis increases with age, signs and symptoms of the disease appear to be mainly connected with infection occurring during fetal life or in childhood. Most of the mothers who have given birth to infected infants have shown laboratory evidence of past toxoplasmic infection; however, none were recorded as having had symptoms suggestive of an acute infection, except for such acute respiratory and gastroenteric diseases that are prevalent in the population as a whole. It is likely, therefore, that acute toxoplasmosis may be asymptomatic in resistant persons (especially in adults) or that it might be accompanied with nonspecific signs and symptoms, suggesting "flu," a gastrointestinal upset, infectious mononucleosis or the like.

Transplacental Toxoplasmosis.—Direct evidence of the antenatal inception of toxoplasmosis was brought forth by Paige, Cowen and Wolf,³⁴ whose fourth patient had intrauterine hydrocephalus necessitating craniotomy for delivery. Autopsy showed advanced subacute toxoplasmosis. Indirect evidence has been accumulated in the several cases reported with neonatal manifestations of widespread and advanced organ involvement characteristic of the subacute disease. The question arises as to whether the mother's initial infection with *Toxoplasma* was contracted during pregnancy or whether she had a chronic latent infection, in the course of which a few organisms escaped from a ruptured pseudocyst, infecting the placenta and hence the fetus. While either of these possibilities appear possible, primary infection of the pregnant mother appears more likely to be the commoner mode of fetal toxoplasmic infection. There is no history of a mother's transferring the disease in more than one pregnancy. None of the mothers with preexisting clinical signs and laboratory evidence of toxoplasmosis subsequently gave birth to infected infants. Conversely, none of the mothers who gave birth to toxoplasmic infants had any signs of the disease, except in 1 case of Heidelman's¹⁹ (case 27), in which chorioretinitis in both the mother and the child was associated with *Toxoplasma*-neutralizing antibodies. However, the mother's only lesion was active eight years after the birth of the infant and there was no evidence that the lesion had been acquired before that pregnancy. The presence of a pronounced hypersensitivity to *Toxoplasma* after the acute infection

makes blood stream dissemination of the organism rather unlikely.⁴¹

Furthermore, the grouping of cases in as rare a disease appears worthy of mention. Patients C. J. and B. D. A., observed by me,⁴ were born on the same day in San Francisco, without any cases having been recognized in the succeeding eighteen months in several hospitals of this city. The 2 patients reported by Sabin (1941) showed symptoms of the disease within ten days of each other in adjacent localities. Zuelzer's patients reported in 1944 were born in Detroit within a week of each other. Pinkerton and Henderson's (1941) cases occurred during the same summer in St. Louis. These data might be interpreted as being indicative of minor epidemics of toxoplasmosis, leading to acute infection of the mothers. With the mode of adult infection not yet definitely established, one can only speculate on an epizootic among arthropod vectors.

DIAGNOSIS OF TOXOPLASMOSIS

The isolation of *Toxoplasma* from a patient is the most significant single datum in the establishment of the diagnosis. Unfortunately, isolation is frequently not possible, leaving one to resort to pathologic, immunologic and serologic methods to confirm impressions gleaned from a patient's history and physical findings. Attempting to base a diagnosis only on one or the other finding appears to be premature in the present state of knowledge of the disease. It is highly desirable that one investigate patients completely, employing every method available, to arrive at a better understanding of the clinical syndromes. The lesions produced and the resulting signs and symptoms have been discussed in the previous sections. In the following section, an attempt will be made to evaluate the available laboratory aids.

Isolation of Toxoplasma.—During the acute stage of the infection, organisms might be recovered from blood, bone marrow, splenic puncture material, cerebrospinal fluid and possibly sputum. During the subacute stage organisms have been found in the ventricular fluid obtained by aspiration and from the central nervous system at autopsy. In the chronic state organisms might be present in the central nervous system, the eye and the myocardium. Visual demonstration of *Toxoplasma* on direct smears is rarely successful, except in the case of ventricular fluid sediments, where organisms have been demonstrated on several occasions during the subacute stage of the infection. Animal inoculations to study the biologic characteristics of the strain are highly desirable. Since chronic latent toxoplasmosis has been observed in many laboratory animals, it becomes necessary to utilize several species in each isolation attempt. Furthermore, the stock animals should be tested for the presence of such chronic latent infection by "blind passage" of their organs (especially brain) to other animals.

The following procedures were most useful in my hands for the isolation of *Toxoplasma* from human or animal sources. The inoculum, such as ventricular fluid sediment, is injected into groups of mice, hamsters and guinea pigs. One group of 4 to 6 animals of each species is inoculated intracerebrally, and a like group is inoculated intraperitoneally. If any of the animals should die, the brain is removed aseptically from animals inoculated by either route and it is subinoculated

41. Recently, Doctor C. D. Binkhorst reported from Holland the concurrence of chorioretinitis in a mother and her daughter (Toxoplasmosis, a monograph, Leiden, Netherlands, H. E. Stenfort Kroese, 1948, case 11; *Ophthalmologica* 115:65 [Feb.] 1948 [case 21]). Ocular lesions were first observed in the otherwise normal child at the age of 5 months; her serum contained *Toxoplasma*-neutralizing bodies when she was 6 years old. It was impossible to determine whether her infection was acquired in utero. Her mother's chorioretinitis is not typical for toxoplasmosis, and the result of her neutralizing antibody test was doubtful.

into other animals. At the same time impression films are prepared, stained with Wright's stain and examined for *Toxoplasma* (fig. 1 B). Intraperitoneally inoculated animals are examined for peritoneal exudate on the sixth and tenth days after injection. They are lightly etherized, and an abdominal paracentesis is performed with a 20 gage needle attached to a 2 cc. syringe. The pooled fluid, which must be obtained under aseptic conditions, is subinoculated intracerebrally into groups of fresh mice, hamsters and guinea pigs. The fluid is then examined either fresh or on a stained film for the presence of *Toxoplasma*. In the case of death of an intraperitoneally inoculated animal, impression films should be prepared from the mesentery, the liver, spleen and lung, and searched for *Toxoplasma*. If none of the animals should have ascites or die within one month, the survivors must be examined for infections that passed asymptotically because of the low pathogenicity of certain (unadapted) strains. Half of the animals of each group are killed after one month and their brains pooled and subinoculated. This single "blind passage" frequently will bring to light a toxoplastic infection present, although occasionally two or more such passages may be needed. The other half of the first inoculated animals should be held until the "blind passage" experiment has been carried to a definite conclusion. They may then be tested for immunity if an organism has been isolated. Most of these animals should be immune to a challenge injection with the homologous strain, although immunity to a heterologous virulent strain may be less pronounced (especially in mice).⁴²

Pathologic Examination.—During the course of the acute infection, biopsies of skin, lymph node, bone marrow, liver and spleen may be available. From patients in the subacute stage ventricular fluid sediment may be obtained and treated like a "button." Various tissues may be available from autopsies of patients in any of the stages of the disease. *Toxoplasma* are easily recognizable in sections stained with hematoxylin and eosin or with one of the polychromic methylene blue dyes. Fixation of tissues in Zenker-formaldehyde is preferable to formaldehyde if cytologic detail is appreciated. Contrary to their elongate appearance in the fresh state or on the dry film, on sections *Toxoplasma* are usually rounded up and nearly spherical bodies of equal size (fig. 1 C and E). Great care must be exercised to distinguish *Toxoplasma* from organisms such as *Histoplasma capsulatum*, *Trypanosoma cruzi*, *Leishmania*, *Encephalitozoon* and *Sarcocystis*.⁴³

Antigenic Test for the Demonstration of *Toxoplasma* Antigen in Ventricular Fluid of Infants with Hydrocephalus.^{4b}—Fluids obtained from ventricular puncture of patients with subacute toxoplasmosis are centrifuged. One-tenth cubic centimeter of the supernatant is injected intradermally into normal guinea pigs and into guinea pigs with chronic latent toxoplasmosis. Ventricular fluids from 2 patients from whom *Toxoplasma* was isolated evoked after twenty-four hours a large area of erythema and induration at the site of injection in the infected guinea pigs. Little or no similar reaction was present in the normal animals. Ventricular fluids

from 4 other hydrocephalic infants without evidence of toxoplastic infection gave negative reactions in both infected and control groups.

On the other hand, ventricular fluid from a patient with *Escherichia coli* meningitis evoked a slight area of erythema and induration in the toxoplastic guinea pigs, but none in the normal controls. Guinea pigs previously injected with human brain or cerebrospinal fluid may not be used, since they show pronounced reactions of dermal hypersensitivity on reinjection with the like material. This test, carefully used, may facilitate a rapid differential diagnosis of neonatal hydrocephalus.

Cutaneous Tests with *Toxoplasma* Antigen (*Toxoplasmin*).—This test^{4b} is the most useful simple aid in the diagnosis of past or latent toxoplasmosis, whenever isolation of the causative organism is not feasible. Intradermal injection of suitable dilutions of toxoplasmin evoke reactions of a delayed (tuberculin) type of hypersensitivity in certain patients. Since 1945 about 300 persons have been investigated for toxoplasmin sensitivity, and high rates of positivity have been found in patients with chorioretinitis, in mothers who have given birth to infected children and others. There is a good correlation between the results of cutaneous tests and *Toxoplasma*-neutralizing antibody tests. When the result of a toxoplasmin cutaneous test is positive, it, is usually followed by the appearance of complement-fixing antibodies to *Toxoplasma* antigen, whereas a negative result does not seem to give rise to such antibodies.

The cutaneous test is most useful in the diagnosis of chronic toxoplasmosis. Patients with acute toxoplasmosis are not expected to acquire dermal hypersensitivity early enough to be diagnostically useful. The test requires further trials in patients with the disease in the subacute stage to evaluate its diagnostic efficiency.

The diagnostic antigen^{4b} is derived from the sediment of mouse peritoneal fluids rich in *Toxoplasma*. The organisms are inactivated, their cell bodies are broken up and the antigen is standardized, tested for sterility and diluted in phenolized saline solution. A control antigen is similarly treated. Both antigens are injected intradermally in amounts of 0.1 cc. Readings are obtained after forty-eight to seventy-two hours, but positive reactions usually are apparent after twenty-four hours. An area of erythema and induration of over 10 mm. with a negative reaction in a control is taken as evidence of past or persistent infection. The intensity of the positive reaction could not be correlated with the degree of clinical activity.

An *In Vitro* Test for Hypersensitivity to *Toxoplasma* Antigen.—Recently Nantz and Blatt⁴⁴ described a method for the evaluation of bacterial hypersensitivity by the application of a tissue culture technic. Their method permits a quantitative analysis of hypersensitivity exhibited by a patient's white blood cells toward a variety of antigens. At present, studies are under way to evaluate the usefulness of this test in the study of toxoplastic infection.

***Toxoplasma*-Neutralizing Antibody Test.**—This test, first described by Sabin and Ruchman,⁴⁵ has been

present at a much earlier age in many of them. Fourteen of the 20 patients (70 per cent) were female.

Evidence for the occurrence of asymptomatic (and later chronic?) toxoplasmosis has been accumulated from the serologic observations associated with dermal hypersensitivity to *Toxoplasma* antigen. A survey conducted by me at the University of California Medical School revealed an incidence of 10 per cent in a group of 50 normal persons between the ages of 20 and 35 years and an incidence of 28 per cent in a group of 50 hospital patients between 50 and 83 years of age. None of these patients had any of the recognized clinical signs of toxoplasmosis, and from only 1 was a history of encephalitic symptoms elicited. Whereas the incidence of past (or persistent?) toxoplasmosis increases with age, signs and symptoms of the disease appear to be mainly connected with infection occurring during fetal life or in childhood. Most of the mothers who have given birth to infected infants have shown laboratory evidence of past toxoplasmic infection; however, none were recorded as having had symptoms suggestive of an acute infection, except for such acute respiratory and gastroenteric diseases that are prevalent in the population as a whole. It is likely, therefore, that acute toxoplasmosis may be asymptomatic in resistant persons (especially in adults) or that it might be accompanied with nonspecific signs and symptoms, suggesting "flu," a gastrointestinal upset, infectious mononucleosis or the like.

Transplacental Toxoplasmosis.—Direct evidence of the antenatal inception of toxoplasmosis was brought forth by Paige, Cowen and Wolf,^{3a} whose fourth patient had intrauterine hydrocephalus necessitating craniotomy for delivery. Autopsy showed advanced subacute toxoplasmosis. Indirect evidence has been accumulated in the several cases reported with neonatal manifestations of widespread and advanced organ involvement characteristic of the subacute disease. The question arises as to whether the mother's initial infection with *Toxoplasma* was contracted during pregnancy or whether she had a chronic latent infection, in the course of which a few organisms escaped from a ruptured pseudocyst, infecting the placenta and hence the fetus. widely used and has proved useful in demonstrating such antibodies as may be found in the subacute and the chronic state of the infection. However, equivocal readings are frequently obtained, apparently because of low titers of neutralizing antibodies.⁴⁶ The antibody titer usually increases after a positive reaction to a toxoplasmin cutaneous test; hence it is useful to employ these two tests in conjunction. Other disadvantages of the neutralizing antibody test include the fact that diagnostic readings require a week to develop and that neutralizing antibodies are unstable both at room and refrigerator temperatures, necessitating storage of test serums in the frozen state. For the performance of the test an active strain of *Toxoplasma* must be maintained in the laboratory. Neutralizing antibodies are demonstrated by their inhibiting effects in *Toxoplasma*-serum mixtures on the development of papulonecrotic cutaneous lesions in rabbits, at the sites of intradermal injection of various dilutions of *Toxoplasma*.⁴⁷ Recently Alm⁴⁸ demonstrated neutralizing antibodies quantitatively on infected chorioallantoic membranes of chick embryos. Since chronic active toxoplasmosis is frequently accompanied by relatively low levels of neutralizing antibodies, it is of interest to check for increase of antibody titers during treatment. Although the serum antibody measured here is not directly related to the degree of dermal hypersensitivity, analogous qualitative results are usually obtained. The patients who give divergent results with these two tests, however, are most interesting to study for possible pathologic implications of this phenomenon.

Toxoplasma Complement-Fixing Test.—This test was first described by Warren and Sabin.⁴⁹ Recently an improvement of this technic was reported by Warren and Russ.⁴⁹ Dr. Carl M. Eklund and Dr. David Lackman performed complement fixation tests with *Toxoplasma* antigen on the serums of many of my patients using a still different technic. Two of their observations will be quoted here, since they are important for correlation with those observations obtained by use of the other tests. Patients who showed a negative toxoplasmin skin test on repeated occasions, did not possess demonstrable complement-fixing antibodies, nor did they develop any in result of these antigen injections. Secondly, patients with positive toxoplasmin skin tests, who usually did not show complement-fixing antibodies in their serum, frequently showed an antibody titer in response to the antigen injections. Pre-existing titers were increased. Titers tended to disappear between one and two years after the patient received the last antigen injection or gave birth to an infected infant. Many patients have shown a positive neutralizing antibody test whereas a complement-fixing test on their serum has been negative. Data obtained by the use of monkeys likewise indicate that the presence of a complement-fixing titer is

indicative of a recent infection or of recent contact with *Toxoplasma* antigen. Judging from the animal data, complement-fixing titers might be detectable within a week after infection. Since at this time neutralizing antibodies cannot be demonstrated unequivocally, the complement-fixing test might prove especially useful in the early stage of the disease, if a rise in titer can be demonstrated (see, however, footnote 47). Its results should be compared, however, with those of the other tests, and, of course, an attempt should be made to isolate *Toxoplasma*.

Clinical Laboratory Data.—The most striking observation is the high ventricular fluid protein content in patients with subacute toxoplasmosis. No other consistent observations have been encountered, and further study is required to establish significant data.

TREATMENT OF TOXOPLASMOSIS

In acute toxoplasmosis the number and severity of lesions are in direct proportion to the number and virulence of the organisms and inversely proportional to the natural resistance of the host. Treatment with sulfadiazine and sulfamerazine in full doses has been observed to control this type of infection in animals. Robinson⁵⁰ reported the successful treatment of a child with predominantly meningoencephalitic signs and symptoms. Treatment should be continuous for about two to three weeks, until sufficient immunity has been acquired to prevent a relapse. As has been shown by Weinman,^{50b} treatment with sulfonamide drugs suppresses proliferation of organisms, but it does not rid the host of these organisms. *Toxoplasma* persists in the form of pseudocysts within neural tissue, and, since antibody titers are much lower there than in the serum the organisms might resume proliferation in the absence of a sufficiently high level of sulfonamide drugs or antibody. The clinical relapse observed by Robinson might be explained on this basis. Supportive treatment, such as oxygen, transfusions (if possible of serum containing neutralizing antibody) and a low fat diet, should be given as indicated. Penicillin,⁵¹ streptomycin, and a number of other drugs⁵² were not found effective in the treatment of toxoplasmosis. Recently, chloromycetin, aureomycin, subtilin, polymyxin-B, chlorguanide hydrochloride (paludrine®), bacitracin, p-aminosalicylic acid, nicotinic acid and nitrofurazone (furacin®) I found ineffective in treatment of experimental toxoplasmosis.

In subacute toxoplasmosis, extensive mechanical and usually irreversible lesions are present by the time the diagnosis is made. Indeed, hydrocephaly, being usually the first suggestive sign, depends on occlusion of the aqueduct and the ventricular foramina. Although treatment with sulfonamide drugs has proved effective in suppressing proliferation of the organisms, a patient observed by me (R. F.),^{4a} died later with extensive central nervous system damage, accompanied with histologic signs of repair and very few organisms. Zuelzer^{29d} has made similar observations, although 1 of his patients survived. In cases of more advanced disease, in which hydrocephaly and chorioretinitis are

⁴⁶ Heidelberg.¹⁰ Frenkel.^{4b}

⁴⁷ An in vitro dye test has recently been developed which is a better tool for the estimation of *Toxoplasma*-neutralizing antibody. The quantitative data obtained by this test provide the most useful information for the serologic diagnosis of Toxoplasmosis. Furthermore, it was demonstrated that the *Toxoplasma*-neutralizing antibody itself is heat stable, that, however, a heat-labile "accessory factor" is necessary to consummate the neutralizing process, in the rabbit test as well as in the in vitro dye test (Sabin, A. B., and Feldman, H. A.: Dyes as Microchemical Indicators of a New Immunity Phenomenon Affecting a Protozoan Parasite [*Toxoplasma*], *Science* **108**: 660 [Dec. 10] 1948).

present, treatment with sulfonamide drugs does not appear to be very promising, and survival may be accompanied with such conditions as mental deficiency, partial or complete blindness, spastic paraplegia and convulsions.

In chronic active toxoplasmosis, lesions are thought to be due to rupture of *Toxoplasma* pseudocysts, such as in the retina, giving rise to localized reactions of hypersensitivity. Consideration of this concept, discussed previously, has led to attempts at desensitization of patients showing active chorioretinitis, associated with evidence of toxoplasmic infection from cutaneous and serologic tests. The rationale of this treatment implies stimulation of increased titers of free plasma and intercellular antibody, capable of binding and neutralizing the antigen in the intercellular fluids, and minimizing the amount of the same reaction taking place on the more vulnerable cell surfaces. High serum antibody levels should be obtained, since their diffusion ratio into the central nervous system and the eye is of very low order.

So far, 9 such patients have been treated by injection of graded increasing doses of *Toxoplasma* antigen, supplemented in some instances by nonspecific protein therapy with intravenous typhoid vaccine.⁴⁰ The lesions became inactive during treatment in 8 patients, as indicated by disappearance of the vitreous exudate, decreased retinal edema and infiltration and beginning pigment deposition. One patient was not improved, and granulomatous iridocyclitis developed in addition to the chorioretinitis. This latter patient also had a positive reaction to a tuberculin test. Since the course of these lesions cannot be predicted, any improvement occurring during treatment cannot necessarily be said to be due to it. The results of this experimental treatment are recorded here to point a way for careful and prolonged clinical research work, which should be controlled by the immunologic and serologic tests previously discussed.

Treatment with sulfonamide drugs does not appear to have a significant effect on *Toxoplasma* pseudocysts. The chorioretinal lesions are thought to be due more to the liberated antigen, which does not quickly diffuse out of the vitreous, than to proliferation of *Toxoplasma* in the retina. In persistent cases of chorioretinitis, treatment with sulfonamide drugs might be given a trial. However, again this treatment may be expected only to inhibit proliferation of organisms. What is needed is a drug that diffuses through the blood-neuroectodermal barrier into the brain and the eye and that kills *Toxoplasma*, rather than merely suppressing its multiplication.

SUMMARY

The classification proposed here is based primarily on the pathogenesis and secondarily on clinical manifestations of toxoplasmosis. Each infection is considered to progress from the acute, to the subacute, to the chronic stage, unless death supervenes. The laboratory tests most useful in the diagnosis of each stage are included in the following outline.

A. *Acute Toxoplasmosis*. Generalized, irrespective of age or mode of infection, involving all viscera, including the central nervous system; diagnosed by demonstration of the organisms (I), rise in complement fixation and neutralizing antibody⁴¹ titers (I, II)

I. *Symptomatic*—pneumonitis, hepatitis, meningoencephalitis, cutaneous rash, etc.

(a) Early predominantly visceral symptoms

1. Infantile cases^{28a, b}
2. Adult cases⁵³

(b) Late predominantly meningoencephalitic symptoms:

1. Infantile cases⁵⁴
2. Adult case⁵⁵

II. *Asymptomatic*—majority of cases, undiagnosed

B. *Subacute Toxoplasmosis*. Depending on persistence and proliferation of *Toxoplasma* in the central nervous system, including the eye; subsidence of other visceral lesions due to antibody formation; zone of antigen-antibody reaction surrounding ventricles; diagnosed by isolation of *Toxoplasma*, antigenic test with ventricular fluid (I), rise in neutralizing antibody titer, positive complement fixation titer (I, II)

I. *Symptomatic*

- (a) Fatal; chorioretinitis, usually with periventricular zones of necrosis, hydrocephaly, cerebral calcifications usually small or absent
- (b) Surviving; chorioretinitis, usually with microcephaly, cerebral calcifications frequently larger, other signs of cerebral damage (electroencephalogram)

II. *Asymptomatic*—majority of cases, no significant lesions; undiagnosed

C. *Chronic Toxoplasmosis*. Depending on persistence of *Toxoplasma* pseudocysts in the central nervous system, the eye and the myocardium; diagnosed clinically by immunologic and serologic tests

I. *Active*—chorioretinitis, anterior uveitis (?); positive reaction to cutaneous test, positive reaction to neutralizing antibody test, positive or negative complement fixation titer

II. *Latent*

(a) *Symptomatic*—chorioretinitis, anterior uveitis (?), microphthalmia, other ocular malformations, microcephaly, hydrocephaly, spastic paraplegia; positive reaction to cutaneous test, positive reaction to neutralizing antibody test, positive or negative complement fixation titer

(b) *Asymptomatic*

1. Mothers who gave birth to infected infant; positive reaction to cutaneous test, positive reaction to neutralizing antibody test, complement fixation titer usually positive for several months thereafter
2. Pseudocysts discovered at autopsy
3. Only evidence: positive reaction to cutaneous test, positive reaction to neutralizing antibody test, complement fixation titer usually negative.

Radiation and Abnormal Children.—The best evidence we have to date is that in humans, in general, radiation will not significantly increase the rate of these mutations. Our studies of the survivors of Hiroshima and Nagasaki (carried on by the Atomic Casualty Commission) thus far fail to disclose any increase whatever of abnormal children, nor has there, thus far, been any increased incidence of still births or miscarriages, or of leukemia. Our Commission will continue to support this extensive work in Japan, the results of which in the course of time will throw a great deal of light on this whole subject of radiation effects—immediate and long-term.—From an address by David E. Lillenthal, Chairman, Atomic Energy Commission, before the American College of Physicians, New York, March 31, 1949.

CULDOSCOPY: ITS DIAGNOSTIC VALUE IN PELVIC DISEASE

ALBERT DECKER, M.D.
New York

Pathologic conditions of the female pelvis that do not permit a positive diagnosis by the routine methods are occasionally suspected or actually encountered. In the presence of inconclusive observations in conditions that require a positive diagnosis, exploration by laparotomy has frequently been employed. It is believed that any safe method of direct study of the pelvic viscera that avoids exposure by laparotomy deserves consideration.

HISTORY

The value of endoscopic visualization is amply demonstrated by its frequent application to the body cavities and hollow viscera by specialists in many fields.

In 1910, Kelling¹ successfully visualized the abdominal viscera through an endoscope by means of abdominal puncture. Ruddock² in 1934 published a report of 900 patients examined by means of a peritoneoscope introduced through the anterior abdominal wall. Abdominal puncture, in the absence of ascites, regardless of the favorable reports of its advocates, has not gained widespread recognition. The critics of peritoneoscopy fear bowel injury, infection, pain associated

with the puncture and the distention of the cavity with gas under positive pressure.

I have applied endoscopy to the pelvis by a technic that avoids the undesirable features of abdominal puncture. Endoscopy through the rectovaginal pouch, commonly termed the cul-de-sac of Douglas, accomplishes this purpose. The procedure is termed culdoscopy.

Fig. 1.—Posterior view of the vaginal canal, with the patient in the knee-chest position. Injection of local anesthetic in the vaginal vault.

Fig. 2.—Posterior view of the vaginal canal, with the patient in the knee-chest position. The trochar is in the cannula, the tip poised over the vaginal vault ready for puncture.

THE PUNCTURE

It is apparent that any complications or accidents that might occur during culdoscopy would result from the puncture rather than from visualization. It is the puncture, then, that must be critically considered.

The surgical anatomic relations of the rectovaginal pouch to the cervix and rectum in the knee-chest position account for the desirable features of culdoscopy. In the knee-chest position the movement of abdominal viscera cephalad creates a negative pressure in the abdominal cavity. This may amount to as much as 35 to 50 cc. of water. The intestines fall out of the pelvis. The posterior vaginal vault becomes exaggerated, stretches and is thinned out, so that it is frequently only a few millimeters in thickness. The vaginal mucous membrane and the peritoneum of the cul-de-sac approximate at the point of greatest concavity. The rectum is separated from the cervix by several centimeters. In this condition the vaginal vault may be easily punctured with needle or trochar with very little discomfort. The puncture is accompanied with the inrush of air which signalizes entry into the peritoneal cavity. A spontaneous pneumoperitoneum amounting to 800 to 1,600 cc. of air may result. Positive gas pressure is not required. Embolism and the extraperitoneal extravasation of air are thus avoided.

Attending Gynecologist, Knickerbocker Hospital; Assistant Attending Gynecologist, New York University-Bellevue Medical Center, University Hospital.

Read before the Section on Obstetrics and Gynecology at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 24, 1948.

2. Ruddock, J. C.: Peritoneoscopy, West. J. Surg. 42: 392, 1934.

The cul-de-sac has been punctured by me and by others³ more than four hundred times with trochar and needle without serious complications.

INSTRUMENT AND EQUIPMENT

A trochar and cannula have been devised to puncture the vaginal mucosa and peritoneum of the cul-de-sac by one thrust without preliminary incision. The cannula is large enough to admit an endoscope designed to view the pelvic organs.

The trochar is grooved and the cannula is equipped with a valve so that carbon dioxide may be introduced into the peritoneal cavity before the trochar is removed. A length of rubber tubing from a container of carbon dioxide may be attached to the cannula valve. When the valve is opened, the gas will be drawn into the peritoneal cavity until the negative pressure is neutralized. Self-retaining cervical cannulas of the screw tip and balloon type have been devised for the purpose of introducing a solution of indigo carmine through the uterus and tubes while they are being observed through the culdoscope.

Fig. 3.—Sagittal section of the pelvis, with the patient in the knee-chest position. The posterior vaginal septum shown at the moment of puncture.

The examining table should be equipped with tall upright leg holders and shoulder braces. Muslin bandages or thigh straps are necessary to support the thigh against the leg holders. Other instruments required are an 8 inch (20 cm.) knee bent vulsellum, perineal retractor, 10 cc. syringe and a 4½ inch (11 cm.) 22 gage needle. Complete operating room facilities are not necessary. A convenient examining room will suffice.

PREPARATION OF THE PATIENT

The vulva is shaved. The bladder and rectum are emptied. One hundred milligrams of meperidine hydrochloride may be given by hypodermic injection forty-five minutes before the examination. Three grains (195 mg.) of amobarbital sodium given orally one hour before the examination has often been satisfactory. In many cases the preexamination medication has been omitted.

THE PROCEDURE

The patient is placed in the knee-chest position, maintained by shoulder braces, leg holders and thigh bandages. The vulva, buttocks and anal region are painted with a nonirritating antiseptic solution. The patient is draped with a sterile sheet or

towels. The perineum is elevated with a perineal retractor. The retracting blade should be applied to the outer three fourths of the posterior vaginal wall. The cervix is grasped with a knee bent vulsellum and drawn down. The point of greatest concavity of the vaginal vault is infiltrated with three or four wheals of 2 per cent procaine hydrochloride, with a 10 cc. syringe and a 4½ inch (11 cm.) 22 gage needle. Five or six cubic centimeters of the anesthetic agent are sufficient. The

Fig. 4.—Sagittal section of the female pelvis, with the patient in the knee-chest position. The trochar has been removed and the culdoscope introduced through the cannula in position for visualization.

tip of the perineal retractor should be adjusted so that it does not extend into the vaginal vault. The perineum and distal three fourths of the posterior vaginal wall should be elevated as high as comfort will allow. The cervix should be drawn down only enough to accentuate the vaginal concavity and to steady the structures during puncture. Forceful traction on the cervix at this moment should be avoided. The trochar and cannula with the valve closed are then poised over the posterior vaginal wall at the point of greatest concavity. This point may be nearer the posterior vaginal wall and rectum than to the cervix. The trochar is then pushed through the vaginal wall with one quick thrust. When the valve on the cannula is opened or if the trochar is removed, air will be heard to enter the

Fig. 5.—Culdoscopic view of an adherent tube and ovary.

pelvis. When it is desired to substitute carbon dioxide for air, the valve is attached to a bag containing carbon dioxide before it is opened. When the inrush of air is not heard or when the carbon dioxide is not drawn into the pelvis promptly, it is obvious that the peritoneal sac has not been entered. Failure to puncture the cul-de-sac results from improper selection of the point of puncture, loosely attached peritoneum with considerable intervening areolar or fatty tissue, or adherent struc-

tures within the cul-de-sac. The last two conditions can usually be apprehended before the examination by a careful pelvic examination and by a preliminary needle puncture. When some doubt is entertained concerning the ability to enter the cul-de-sac in a particular case selected for culdoscopy, preliminary puncture should be employed. On the clinic or office examining table the patient is placed in knee-chest position. The vaginal vault

Fig. 6.—Culdoscopic view of adhesions about a cystic ovary and chronically inflamed tube.

is punctured with a $4\frac{1}{2}$ inch (11 cm.) 19 gage needle attached to a 2 cc. syringe with the plunger drawn out two-thirds its length. Anesthesia is not required. When the needle point enters the peritoneal cavity the plunger of the syringe will be drawn down sharply. The needle is removed without allowing air to enter the abdomen. Inability to demonstrate intra-abdominal negative pressure by this means should usually exclude the patient from further attempts at puncture. In a few instances, when the peritoneum was loosely attached and rode ahead of the tip of the trochar, it was possible to immobilize it by means of a clamp inserted through the mucous membrane wound, while the trochar was reinserted through the same wound, or at another point for a successful puncture.

Our experience warrants the conclusion that cul-de-sac puncture for any purpose, when the pouch is not distended with fluid or blood, should be made in the knee-chest position. When a flexible cannula is used, the dorsal position may be assumed after puncture for removal of fluid, blood or cellular debris.

Culdoscopic Visualization.—After puncture has been accomplished and the selected type of pneumoperitoneum produced,

Fig. 7.—Culdoscopic view of the ovary with follicular cyst.

the trochar is removed while the cannula is held in place. The perineum may be relaxed, but the retractor kept in place. The sterile culdoscope, with dry warm lenses, is inserted into the pelvis through the cannula and locked in place. The illuminated end of the culdoscope will rarely come in contact with any structure. The nature of the septum and the construction

of the cannula allow a wide range of motility of the culdoscope in every direction. It can be freely rotated so that the uterus, ovaries, tubes, broad ligaments, uterosacral ligaments, infundibulopelvic ligaments, anterior rectal wall, pelvic peritoneum, and occasionally the appendix and loops of bowel that do not fall out of the pelvis in this position, can be inspected. The viscera can be manipulated by movement of the vulsellum or by suprapubic manual pressure. The novice will require a little practice to orient himself on viewing the pelvic organs for the first time from this direction.

When detailed information concerning the tubes is desired 10 to 15 cc. of sterile indigo carmine solution may be injected through the self-retaining cervical cannula. A completely obstructed tube shows distention proximal to the point of obstruction. A partially obstructed and adherent abdominal ostium shows extravasation of the fluid under the adhesions. Patent tubes are demonstrated by the dripping of the dye from the fimbria.

When a specially designed culdoscope is employed, material for biopsy may be recovered. The contents of small cysts and follicles can be aspirated and thin adhesions interrupted. Material for smear, culture, biopsy or cytologic examination may be recovered through the puncture wound. The pelvic organs have been successfully photographed through the instrument.

Removal of the Cannula.—When the examination is concluded, the culdoscope is removed, but the cannula is held in

Fig. 8.—Culdoscopic view of the ovary with a recently ruptured graafian follicle.

place. A pillow is placed under the abdomen. The shoulder braces and thigh straps are removed, and the patient is allowed to lie on her abdomen on the table over the pillow. The head of the table may be lowered. The air or carbon dioxide will be heard to rush out of the abdomen, through the cannula, as the abdomen is compressed. When carbon dioxide has been introduced, little concern about removal is necessary. Oxygen is absorbed slowly, and appreciable amounts may remain for several days.

Postexamination Care.—The wound in the posterior vaginal vault is not sutured. Many patients walk from the table. Intra-peritoneal air may give variable amounts of distress on standing, but, as in tubal insufflation, it is not prohibitive of ambulation.

The patient is instructed not to douche for one week. Assumption of the knee-chest position before the puncture is healed may result in a spontaneous pneumoperitoneum. The instrument may be reintroduced through the puncture wound before it is healed. There is no contraindication for repeated punctures.

EXPERIENCE WITH CULDOSCOPY AND SELECTION OF CASES

In a previous report,⁴ in 1946, I discussed a large group of patients examined over a period of three and one-half years. Some of the patients included

4. Decker, A.: Pelvic Culdoscopy, in Meigs, J. V., and Sturgis, S. H.: Progress in Gynecology, New York, Grune & Stratton, Inc., 1946, pp. 95-105.

in that report were examined during the time the instrument and technic were being developed.

It is the purpose of this report to relate the experience with 77 cases selected because they presented diagnostic problems that could be placed in one of four groups.

The diagnostic indications for culdoscopy may be summarized as follows:

Group A—Emergency surgical conditions, differential diagnosis of tubal pregnancy, acute appendicitis, acute salpingitis and the like.

Group B—Problem cases of long duration, when pelvic disease is suspected or cannot be excluded; e. g., pelvic tuberculosis, endometriosis, chronic pelvic inflammatory disease and neoplasms.

Group C—Menstrual disorders, such as dysmenorrhea, menometrorrhagia and amenorrhea.

Group D—Infertility study, when visualization of the tubes and ovaries is desired.

Group A, the Emergency Surgical Group.—These are cases in which emergency surgical treatment was being considered for suspected tubal pregnancy or appendicitis. When the symptoms and signs are atypical the differential diagnosis may be difficult.

Fig. 9.—Culdoscopic view of cystic oophoritis, showing distention of the tube with indigo carmine proximal to the point of obstruction.

Prior to the employment of culdoscopy, tubal pregnancy in its atypical form accounted for a large percentage of the diagnostic errors in this category. Hemoperitoneum can usually be diagnosed by cul-de-sac needling without visualization when the needle is introduced into the rectovaginal pouch, with the patient in the knee-chest position, by the described technic.⁵ Blood elements, when present, will practically always be recovered by this method. In the absence of appreciable amounts of free blood and when the history and physical observations are suggestive of atypical tubal pregnancy, culdoscopy should precede laparotomy.

Among the cases here reported, there were 11 instances when the possibility of tubal pregnancy existed and a correct diagnosis appeared desirable. The culdoscopic examination established the following diagnoses in this series: salpingitis (4 cases), early intra-uterine pregnancy (1 case), cystic oophoritis (1 case), normal pelvis (1 case), tubal pregnancy (2 cases) and ruptured follicle cyst (1 case). In 1 instance the culdoscopic examination was impossible. Salpingitis was found at operation.

Atypical salpingitis may at times be difficult to differentiate from acute appendicitis without too much delay.

The acutely affected tube may be readily visualized and smears or cultures may be obtained from the inflamed region.

In 10 instances the differential diagnosis was between acute appendicitis and salpingitis. In 2 such cases a normal pelvis was encountered at culdoscopic examination, so that a diagnosis of appendicitis was made in

Fig. 10.—Culdoscopic view of the scar of a healing ruptured follicle.

1 case by exclusion of pelvic disease and the other by visualization of the diseased appendix. Subsequent operations verified the diagnosis in both cases.

In 6 instances tubal inflammation was the diagnosis made after cul-de-sac puncture. The puncture was unsuccessful in 2 cases.

It is a fair assumption that a few nonoperative patients in this group would have had laparotomies if a preliminary culdoscopic diagnosis had not been made. The operative diagnosis in 1 of the cases of unsuccessful puncture was salpingitis. At any rate, the diagnostic problem with few exceptions was quickly solved.

Group B, Problem Cases of Long Duration.—In this group lower abdominal pain and various symptoms referable to the lower part of the abdomen and pelvis occurred without demonstrable pathologic changes. They are of interest because their problems were in several instances brought to the gynecologist by the medical and surgical staff. Several cases had remained unsolved after thorough diagnostic study in the clinic and hospital and after various therapeutic measures had been tried without success. When the presumptive diagnosis was either psychoneurosis, residual pelvic

Fig. 11.—Culdoscopic view of a small adenomyoma—posterior surface of the corpus.

inflammatory disease, pelvic adhesions, early endometriosis or tuberculosis, I have frequently applied culdoscopy. The information gained has often made it

5. Decker, A.: Posterior Colpotomy for Diagnosis of Pelvic Diseases, *Am. J. Surg.* 73: 313, 1947.

possible properly to evaluate the indications for or against surgical intervention.

There were 23 such cases. A brief summary of 3 cases follows.

CASE 1.—I. C., a 31 year old tripara, was admitted to the medical service on Dec. 22, 1947, with pyelitis and an enlarged spleen. After control of the urinary infection the patient had a moderately febrile course for thirty-two days before culdoscopic examination. The exact cause of the temperature, which ranged from 99 to 101 F., was not determined after thorough clinical study. Bimanual pelvic examination and pelvic pneumograms were not illuminating. Culdoscopy revealed subacutely inflamed tubes and two small intramural myomas. Sufficient pelvic fluid was obtained for guinea pig inoculation and paraffin block preparation. The fluid contained many polymorphonuclear cells but no tumor cells. Results of guinea pig inoculation were reported negative for tuberculosis.

CASE 2.—Mrs. A. M., a white bipara aged 54, was admitted to the hospital on Sept. 12, 1947, complaining of pain in the right lower quadrant of the abdomen. The onset was three weeks before admission and followed an attack of diarrhea. The pain was aggravated by her standing or walking and radiated to the right groin and suprapubic region. Twenty-four hours after admission there was pain in the right subcostal region.

The history revealed that a right radical mastectomy had been performed twelve years previously, with a pathologic diagnosis of medullary carcinoma, grade 3. Operation was followed by radiation therapy to the chest. In 1939, a right intraligamentous benign cyst was removed. In 1940, the patient was sterilized with roentgen rays for functional bleeding.

She was well nourished and did not appear acutely or chronically ill. A complete clinical study, including physical and laboratory examinations, as well as roentgenograms of the chest and gastrointestinal tract, did not permit a positive diagnosis. The right side of the diaphragm showed slight elevation and very little motility. Results of the bronchoscopic examination were normal. There was no clinical evidence of ascites.

Cul-de-sac puncture with the patient in the knee-chest position resulted in an air pneumoperitoneum and was followed by a roentgenogram of the upper part of the abdomen and the chest with the patient in the upright position. The presence of subphrenic air outlined the upper border of the liver and revealed encapsulated material above the liver. At the time of puncture about 8 cc. of fluid was aspirated from the pelvis. Paraffin block prepared from the sediment of this fluid revealed cancer cells. This diagnosis was subsequently verified by biopsy of the omentum by surgical exposure which revealed metastatic breast carcinoma.

CASE 3.—P. P., a 26 year old childless Negro housewife, was admitted by ambulance to the surgical ward on March 11, 1948, complaining of pain in the right lower quadrant of the abdomen, nausea and epigastric distress.

A similar but less severe attack had occurred one year previously. Menses began at age 14 and, except for moderate menstrual pain for one day, were regular and normal. The last menstrual period had been on February 23. There were no urinary symptoms or vaginal discharge.

In appearance, the patient was well nourished but acutely discomforted by pain in the right lower quadrant of the abdomen. The abdomen was tender in this region, with slight rebound tenderness and voluntary muscle spasm. Pelvic palpation revealed as the only abnormality some tenderness on motion of the cervix.

The temperature was 99 F., pulse rate 90, respirations 22 and blood pressure 130 systolic and 90 diastolic. Sedimentation rate was 14 mm. in one hour; hemoglobin was 11 Gm. (75 per cent), erythrocytes 3,900,000 and leukocytes 12,000, with 75 per cent polymorphonuclear cells. The urine contained no sugar or albumin, and results of microscopic examination of the sediment was not remarkable.

On the day of admission, the appendix was removed through a McBurney incision. Results of palpation of the pelvic organs at this time were reported normal. No histologic changes of significance were found in the appendix.

The postoperative course was uneventful until the sixth postoperative day. While sitting in a chair the patient had a sudden attack of severe abdominal pain with fainting. The temperature was 98.6 F., pulse rate 88 and blood pressure 120 systolic and 80 diastolic. No change of significance had occurred in the blood cell count. The lungs were clear, and the heart presented no abnormalities.

The abdomen was tender in the left lower quadrant. Thorough pelvic palpation was unsatisfactory because of acute tenderness. The uterus was normal in size and very tender on attempt at motion. There was a soft baggy painful mass (4 cm. in diameter) in the cul-de-sac. The cul-de-sac was needled in the dorsal position, and about 4 cc. of blood-stained fluid was recovered. Smear of the fluid disclosed red blood cells and many leukocytes. *Staphylococcus aureus* was cultured from the fluid. The diagnosis was changed from tubal pregnancy to pelvic inflammatory disease. The acute symptoms subsided.

Culdoscopic examination was advised in order further to confirm the diagnosis before the patient's discharge and because she desired an opinion as to the cause of three and one-half years of infertile marriage. Culdoscopic examination on March 25 revealed the uterus to be normal in size and position. The left ovary was normal in appearance, free from adhesions, and contained a ripening follicle. The left tube presented evidence of acute inflammation, and the fimbria was adherent to the posterior surface of the left broad ligament. The right ovary was adherent and contained a follicle cyst 3 cm. in diameter. The right tube was acutely inflamed. A loop of intestine was adherent at the brim of the pelvis on the right side. Small amounts of fluid removed contained innumerable polymorphonuclear cells and a moderate number of mononuclear cells. Culdoscopy was a distinct aid in the quick solution of this surgical problem.

My co-workers and I have, on other occasions, applied culdoscopy for indications a short time after laparotomy when it was believed that visualization at the time of operation was not complete because of the type of incision. On one occasion small endometrial implants were observed that were not included in the laparotomy observations.

Two patients in this group were examined preoperatively because there was a difference in opinion concerning the exact diagnosis and the advisability of operation. An ovarian cyst was visualized in one, and in the other chronically thickened and adherent tubes. The culdoscopic diagnoses were confirmed at surgical exposure.

Another patient had an undiagnosed febrile hospital course of thirty-eight days on the medical service before culdoscopy was employed. Unsuspected serosal tubercles of the bowels were visualized. The pelvic organs were normal. No previous evidence of tuberculosis had been obtained. The diagnosis was subsequently further confirmed by positive microscopic observations in cervical glands.

Three patients treated in the hospital for acute pelvic inflammatory disease were examined by culdoscopy before discharge to the clinic. These were patients in whom persistent symptoms or signs created a suspicion of tuberculosis, endometriosis and cystoma. These conditions were ruled out in each instance.

The puncture was unsuccessful in 1 instance. In the remaining cases of this problem group, the visual diagnosis was a valuable aid in the selection of the proper therapy.

Functional disturbance of the nervous system with symptoms referable to the pelvis is a common problem that confronts the gynecologist with increasing frequency. One cannot arrive at a conscientious diagnosis of psychosomatic disease without positively excluding actual disease. It is possible that this group accounts for a large percentage of the unnecessary elective opera-

tions and exploratory laparotomy. Our experience leads us to believe that mistakes are also made in the other direction, and the patient with a real but nonpalpable pathologic condition is at times classified as neurotic.

In 4 such cases, culdoscopic visualization warranted the removal of the patient from the surgical to the psychosomatic group. Three patients had been considered psychosomatic after a long period of clinic attendance. Culdoscopic visualization demonstrated pelvic inflammatory disease and adhesions in amounts sufficient to account for the symptoms in 2 cases. Endometriosis was the visual diagnosis in the third patient.

Group C, Menstrual Disorders.—In this group the symptoms were amenorrhea, dysmenorrhea or other previously unexplained menstrual abnormalities. Seventeen cases comprise this group. The symptoms were present in nearly all cases for a long time. Many of the patients had been subjected to various diagnostic procedures and had received therapy of several types for extended periods without relief of the symptoms. The following case is illustrative.

CASE 4.—G. C., a 31 year old English war bride, sought relief in December 1947 for primary amenorrhea and sterility. There were no other complaints. This 128 pound (58 Kg.) white woman was well nourished and apparently in excellent health and regularly employed as a secretary. She had until recently engaged in competitive swimming events. There was no physical evidence of endocrine disturbance. Endocrine therapy of various types had been employed for several years. The most frequent previous diagnosis had been endocrine amenorrhea, primarily ovarian.

The results of the physical examination were essentially normal. Roentgenograms of the chest and pituitary did not reveal any evidence of disease. The endometrial biopsy diagnosis was atrophic endometrium. There was no evidence of extensive pelvic disease. A cystic mass, 3 cm. in diameter, was palpable in the left ovarian region.

On culdoscopic examination, a grayish white area, 1.5 cm. in diameter and slightly elevated, was observed on the uterine serosa at the fundus. The right tube was thickened and fixed and presented two small serosal tubercles. There was a serosal cyst 3 cm. in diameter on the posterior surface of the left broad ligament. The ovaries appeared white and sclerotic. There was no evidence of follicular activity. The culdoscopic diagnosis of pelvic tuberculosis was confirmed at operation.

There were 3 cases of severe dysmenorrhea. The condition in 1 was primary and in 2 acquired. Their problems were unsolved after thorough clinical study and extensive trial of therapeutic measures by several gynecologists. The culdoscopic diagnoses in these cases were: adenomyosis of the uterus, endometriosis of the ovary and chronic salpingitis. The diagnosis was confirmed in each instance by laparotomy. Abnormal menstrual bleeding was present in 3 other cases, brief descriptions of which follow.

CASE 5.—There was postmenopausal bleeding in a 62 year old white woman. Curettage was done on two occasions, at eight month intervals, and the diagnosis was hyperplastic endometrium. An ovarian tumor was suspected but was not palpated. Culdoscopic visualization disclosed the left ovary transformed into a solid white smooth surface tumor 3 cm. in diameter. Laparotomy confirmed the culdoscopic impression of granulosa cell tumor.

CASE 6.—A white multipara, aged 32 years, had irregular menstrual flow lasting from five to as many as forty days during the three years prior to examination. This complaint was unrelieved after extensive diagnostic and therapeutic measures. She was admitted to the hospital for removal of a cystic ovary. Culdoscopic examination revealed a normal pelvis without evidence of disease.

CASE 7.—A 25 year old married housewife had lower abdominal pain in recurring attacks for fourteen months. She

experienced severe dysmenorrhea and irregular bleeding. This was the second hospital admission in less than a year. The diagnosis at discharge eight months previously was acute pelvic inflammatory disease, and the patient was referred to the clinic for treatment. Regular clinic attendance for eight months did not result in relief. She was again referred to the ward for surgical treatment with the diagnosis of tubo-ovarian disease. Culdoscopic examination after admission revealed an entirely normal pelvis with normal-appearing tubes and ovaries. She was not operated on.

Nine patients (aged 23 to 28) had as their chief complaint abnormal bleeding with irregular intervals and increase in duration of the flow. Variable amounts of menstrual pain were also present. In each instance the symptoms had been of several months' duration and the exact cause was not determined. Salpingitis with adhesions was the unsuspected diagnosis in 2 instances. In 2 cases the pelvic organs were normal in appearance. In 3 cases the presence of suspected pelvic inflammatory disease was confirmed, and the exact extent of the disease noted. Two punctures were unsuccessful.

Group D, Infertility Problems.—The cases that I choose to report here were examined after long periods of infertile mating. The routine investigations were made previous to culdoscopic visualization by competent investigators.

In 16 instances, the visualization was for the purpose of answering one of two questions. Is this particular pelvis entirely free of disease as the routine investigators indicated? If so, what is the functional appearance of the ovaries? In the second instance, the problem has been presented as follows. There is evidence of pelvic disease—tubal, ovarian or uterine. Can the actual extent and location of the disease be determined in detail so that a more conscientious opinion can be given concerning further therapy or the chances for surgical relief?

In 13 cases I was able to answer that question in detail, in the more recent cases by photographs in color. I have found disease when the pelvis was believed to be free from disease. Adhesions causing various types of derangement of the ovarian tubal relations have been disclosed when the investigation before culdoscopic examination indicated more extensive disease. Endometriosis was visualized in 2 cases in this group. In 1 instance it was an unsuspected observation.

In 3 cases puncture was unsuccessful—visualization was not possible. In another group of cases of sterility there was a large percentage of failures, so that at present, in order to avoid the unnecessary preparation for the procedure, I resort to preliminary needle puncture, before arranging for culdoscopic examination.

COMMENT

Pelvic pain, menstrual irregularities and dysmenorrhea, as well as sterility, may be produced by many types of pelvic lesions that are not readily palpable. Frequently their presence is suggested by the history, but occasionally such evidence is absent or misleading.

Endometriosis is a frequent cause of these complaints. The severity of the pain may not bear any relation to the extent of the disease. Endometriosis can be seen before it can be felt. The appearance is distinctive and would rarely be confused with other pathologic changes. Arrest of this disease in young women without castration requires a diagnosis while the disease is still resectable. I have recognized these small lesions on the peritoneum, broad ligament, uterus and ovary on several occasions during culdoscopic examination. Fal-

lon⁶ has aptly stated that to the eye endometriosis is as unmistakable as chickenpox.

When tuberculosis appears as serosal tubercles on the uterus, tubes, bowel or peritoneum, it also presents a distinctive appearance. One may also recognize caseous material as it exudes from the fimbrial end of a thickened tube. The recognition by culdoscopic visualization of this condition when neisserian infection or endometriosis is suspected is particularly gratifying.

Many gynecologists have experienced the chagrin that results from failure to diagnose tubal pregnancy after employing all the usual diagnostic methods. The visual diagnosis is distinctive and readily obtained.

The exploratory laparotomy has a definite place in pelvic surgery. Some critics are of the opinion that pelvic organs containing only a minimal amount of disease are too frequently removed when surgically exposed. Diagnosis by culdoscopy in such cases frequently permits further deliberation to temper the judgment.

SUMMARY AND CONCLUSION

With the patient in the knee-chest position, the rectovaginal pouch may be punctured by needle or trocar by a technic that is simple and safe. Endoscopic visualization of the female pelvis was attempted in 77 cases, when the diagnosis made by other means was indefinite or doubtful. The examination was successful and of diagnostic value in 88.3 per cent of the cases selected. The puncture was unsuccessful in 9, or 11.7 per cent, of the cases. When the puncture was possible, detailed information was obtained concerning the pelvic disease present.

The procedure was particularly useful in disclosing 2 cases of tuberculosis, 4 cases of endometriosis and 1 each of adenomyosis and ovarian neoplasm.

The culdoscopic diagnosis was verified at operation or by subsequent events in all cases. On occasions exploratory laparotomy in suspected surgical emergencies was avoided. A more prompt diagnosis has in some instances resulted in reduction of days of hospitalization and in the number of clinic visits. The procedure has been useful in the solution of problems of menstrual abnormality. In 13 selected infertility problems detailed information was gained concerning the condition of the tubes and ovaries.

There were no serious complications or accidents in these cases. Culdoscopic visualization is a useful and harmless diagnostic procedure that allows a prompt and positive diagnosis in a large variety of gynecologic problems not readily diagnosed by the usual methods.

ABSTRACT OF DISCUSSION

DR. R. W. TE LINDE, Baltimore: It was Dr. Decker's cleverness in seeing the advantage of the knee-chest posture that has made culdoscopy a successful and practical procedure. My co-workers and I have been interested in visualization of the pelvic organs, and we used extensively the ordinary transabdominal peritoneoscopic approach. We found it useful, but not nearly as useful or practical as culdoscopic visualization. I attempted culdoscopic examination with the ordinary peritoneoscope with the patient in the lithotomy position. I was unsuccessful because the crowding of the intestines about the end of the peritoneoscope. Decker overcame this by the use of the knee-chest posture, and, using his technic, we have employed culdoscopic examination in 85 women in our clinic in the past two years. Culdoscopy has several advantages over transperitoneal peritoneoscopy. In ordinary peritoneoscopic

examination one has to transverse many loops of bowel to get to the pelvis. These loops of bowel may be troublesome. In peritoneoscopy one must pump air into the peritoneal cavity. In culdoscopy air rushes in spontaneously. In peritoneoscopy one runs the risk of contaminating the peritoneal cavity on withdrawal of the peritoneoscope if pus is encountered in the pelvis. In culdoscopy no harm is done if one encounters pus, and even drainage may be derived from the cul-de-sac puncture. In peritoneoscopy abdominal adhesions may prevent the end of the peritoneoscope from reaching the pelvis. Cul-de-sac adhesions and tumor occupying the cul-de-sac are the only mechanical contraindications to culdoscopy, and careful pelvic examination will usually detect these before culdoscopic visualization is attempted. Our indications for culdoscopy have corresponded with those of Dr. Decker. We have used it oftenest in cases of suspected tubal pregnancy, and we have no reason to suspect that the information obtained by culdoscopy has been fallacious. One of the most constant sources of worry to the gynecologist is the slight ovarian enlargement which may be due to a retention cyst, which does not require removal, and a neoplastic cyst or tumor, which does. Culdoscopic visualization usually enables one to decide this promptly. Concerning the woman with pelvic symptoms and normal or minimal observations on pelvic examination, is she to be treated for organic pelvic disease or on a psychosomatic basis? Mistakes are made in both directions, but fewer will be made if the culdoscope is used to visualize the organs. There is one point in technic that I want to emphasize. In his fear of injuring the rectum the novice is apt to puncture too close to the cervix, dissect up the peritoneum as it is reflected onto the cervix and thus fail to enter the peritoneal cavity. The thinnest point of the septum is usually 2 to 3 cm. from the reflexion of the vaginal mucosa onto the cervix. The rectum has been punctured only once on our service. This puncture was extraperitoneal and healed spontaneously without even temperature elevation.

DR. W. D. BEACHAM, New Orleans: I agree with Dr. Decker that in suspected hemoperitoneum, cul-de-sac aspiration is a valuable diagnostic procedure. I ordinarily place the patient in a dorsal position. Needling of the cul-de-sac with the patient in the knee-chest posture should be performed prior to attempted culdoscopic visualization in cases in which the advisability of endoscopic examination through the rectovaginal pouch is doubtful. I have not found it necessary to employ culdoscopic examination in patients for whom the diagnosis was narrowed down to appendicitis or ectopic pregnancy. Also, I do not deem it advisable in the differentiation of acute salpingitis from acute appendicitis. Group B cases, as pointed out by Dr. Decker, form the largest category in which culdoscopy is most useful. In these cases one may gain information which makes it possible to evaluate the indications for or against operation. Next in my experience are cases in classification D. The essayist has been overmodest in mentioning the simplicity of this procedure. However, even in his expert hands the puncture was unsuccessful in 11 per cent of his cases. My co-workers and I have investigated the subjects of analgesia and position. In some nulliparous patients we have resorted to preoperative medication, consisting of seconal[®] sodium (sodium 5-allyl-5-[1-methylbutyl] barbiturate, meperidine hydrochloride and scopolamine, and employed pudendal block and local infiltration anesthesia. Now we are checking on the feasibility of intrathecal anesthesia. In our more recent cases we have used a position which requires an operating room table with a kidney elevator. With the patient well sedated we place her in a dorsal lithotomy position, aseptically catheterize the urinary bladder and then thoroughly prepare the vulva and vagina with soap and water followed by the application of benzalkonium chloride or merthiolate[®] solution (sodium ethylmercurithiosalicylate). The patient is then turned over into a prone posture. With her thighs resting on the kidney elevator the anterior abdominal wall hangs in such a manner as to cause the required negative pressure for easy local anesthetization of the area to be punctured and for good visualization with the culdoscope. Even though the patient is well analgized, thigh straps and leg holders are not needed. The table alone supports her. This position is easy on both patient and culdoscopist.

6. Fallon, J.; Brosnan, J. T., and Moran, W. G.: Endometriosis: Two Hundred Cases Considered from Viewpoint of the Practitioner, New England J. Med. 235: 669, 1946.

DR. IRVING F. STEIN, Chicago: At Michael Reese Hospital, Chicago, we have employed gynecography for pelvic diagnosis in the past twenty-five years, in preference to culdoscopy. As in culdoscopy, pneumoperitoneum is utilized; however, we rely on visualization on the roentgenogram for diagnosis. All of the evidence which can be obtained by culdoscopic visualization can likewise be recorded on the roentgenogram except for color of the organs. Gynecography is a far less formidable procedure and is of particular value for consultation purposes. Unlike culdoscopy, in which only the examiner interprets the observations, pneumoperitoneum presents a permanent record which is available for numerous opinions.

DR. ALBERT DECKER, New York: It is gratifying to hear that others have found culdoscopy valuable. I want to thank Dr. Te Linde and Dr. Beacham for their discussion and for their contribution to this subject. I have been asked the reason for the unsuccessful punctures among the cases reported. Puncture cannot be accomplished in all cases. This is either because of loose attachment of the peritoneum, so that it rides ahead of the trocar, or because of the presence of a pelvic mass or adhesions. It is my practice to make a preliminary puncture in the office or clinic in doubtful cases. If I can measure intra-abdominal negative pressure with a small needle, I am certain that the pelvis can be punctured with the trocar.

NEEDLE BIOPSY OF THE LIVER

Cincinnati

During the past four years needle biopsy of the liver has been carried out at the Cincinnati General Hospital 403 times on 345 patients. There has been no fatality or hemorrhage severe enough to require blood transfusion. In 1947, we reported experiences with 195 biopsies made on 170 patients.¹ The present report serves to describe our experience to date, since, during the past year, 208 additional biopsies have been performed on 175 patients.

The patient is prepared for the procedure by the administration of 50 to 100 mg. of mepéridine hydrochloride N. N. R. (demerol®) hypodermically approximately one-half hour before the biopsy.² A liver extending 5 cm. or more below the right costal margin may be approached anteriorly or transpleurally. A smaller liver is approached transpleurally in the right anterior or midaxillary line. In our group of patients, the transpleural route was used 328 times and the anterior approach, 75 times.

METHOD

In the transpleural method the upper limit of liver dullness is suitably marked during ordinary respiration, usually in the anterior axillary line. The area chosen is sterilized with

iodine tincture U. S. P. and alcohol and draped with sterile towels. The operator wears sterile rubber gloves. The skin, subcutaneous tissue, intercostal muscle, pleura, diaphragm, Glisson's capsule and hepatic substance are infiltrated with 2 per cent procaine hydrochloride solution, care being taken to penetrate beyond the intercostal space only while the patient is holding his breath at the end of full expiration. Approximately 8 cc. of procaine hydrochloride solution is used. A small incision is made in the skin over the procaine bleb with a no. 11 Bard-Parker blade to permit easy entry of the biopsy needle. The Vim-Silverman needle³ is introduced into the incision, with the forked obturator inserted in such a position that its tip is just visible at the distal end of the carrier needle. Then, after the patient inhales and exhales deeply two or three times, he is instructed to hold his breath at the end of expiration and the needle assembly, in the position described previously, is inserted a distance of approximately 6 cm. (2 to 3 cm. into the substance of the liver). The obturator is then pushed firmly the final 2.5 cm. into the needle, while the latter is held steady, after which the obturator tip is held steady while the carrier needle is advanced over the obturator, bringing the assembly back to its original relations, but advanced 2.5 cm. farther into the liver. This cores a fragment of hepatic tissue 1 to 2 mm. in diameter and 1 to 2 cm. in length and grasps it tightly in the obturator fork. The entire assembly is rotated approximately 120 degrees, breaking the terminal attachments of the fragment to the liver, and is then withdrawn from the patient. (The average time elapsing between entry of the Vim-Silverman needle into the substance of the liver and its removal is five to ten seconds.) A simple dressing is applied, and the patient is instructed to remain quietly in bed for twenty-four hours. A synthetic vitamin K preparation, 10 mg., is administered parenterally immediately after the biopsy is accomplished, and codeine is used to control any postbiopsy pain. One half of the biopsy specimen is fixed in a 10 per cent solution of formaldehyde U. S. P. (formalin®); the other half is fixed in acetone for special stains. As described in a previous paper,¹ if hepatic tissue is not obtained on the first attempt, additional attempts are made at the same site. This practice has decidedly reduced the number of failures and has resulted in no demonstrable harm to the patient.

INDICATIONS

The following are considered proper indications for needle biopsy of the liver:

1. Hepatomegaly of undetermined cause.
2. Need for distinction between parenchymal and extrahepatic obstructive jaundice. The changes characteristic of infectious hepatitis, the most frequent form of parenchymal jaundice, were well described by Dible, McMichael and Sherlock⁴ and by Mallory,⁵ and those of obstructive jaundice by Roholm and Krarup,⁶ Popper and Franklin⁷ and McMichael.⁸
3. Primary or metastatic neoplasm of the liver. Our experiences with cases of neoplasm of the liver will be published elsewhere.⁹ In this entire study, primary or secondary neoplasm of the liver was demonstrable by means of needle biopsy in 41 of 53 cases. In the case of an enlarged and nodular liver, it is theoretically desirable to insert the needle anteriorly into a nodule.

The study was aided by a grant from the Henry Meiss Fund. Dr. Cogswell, Dr. Safdi, Dr. Richfield and Dr. Kumpe were Fellows of the National Cancer Institute, 1947 and 1948.

Dr. W. E. Molle and Dr. H. H. Steinberg performed some of the biopsies and Dr. Ben Friedman compiled some of the data included in this report.

From the Departments of Internal Medicine and Pathology, College of Medicine, University of Cincinnati, and the Gastric Laboratory of the Cincinnati General Hospital.

Read in part before the Section on Gastroenterology and Proctology at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 23, 1948.

2. We have been carrying out this practice as advocated by Volwiler and Jones (The Diagnostic and Therapeutic Value of Liver Biopsies with Particular Reference to Trochar Biopsy, New England J. Med. 237: 651, 1947) since January 1948. Prior to that time, no sedative was given before biopsy.

4. Hepatic cirrhosis. The type of cirrhosis present may be elucidated by liver biopsy. Rarely, a nodule of hyperplasia may be entered by the needle, in which case the increased fibrosis and other structural abnormalities characteristic of cirrhosis may be missed. Because of the fibrosis, it is somewhat more difficult to take biopsy specimens of cirrhotic livers than of those which are the site of hepatitis or neoplasm. In the presence of ascites, it is necessary to drain off as much ascitic fluid as possible in order to keep the liver from floating away from the needle.

5. Determination of progress of hepatitis. Biopsy is of particular value in patients with minimal or equivocal laboratory evidence of hepatic damage or in those with the "posthepatitis syndrome."¹⁰

6. Evaluation of therapy. In certain instances of hepatic disease, histologic improvement may occur in the absence of corresponding improvement in the results of laboratory tests or vice versa. Microscopic examination of serial biopsy specimens in these cases may demonstrate correction of the cytologic or structural derangement following treatment. In fatty infiltration of the liver, diminution in the extent of the lesions may be demonstrated in the absence of demonstrable laboratory or clinical change.

7. Unrecognized systemic disease. Pathologic changes in the liver may be demonstrated in many diseases in the absence of signs of hepatic involvement. The lesions, when correlated with other clinical and laboratory findings, may make the diagnosis clear. Included among such diseases are miliary tuberculosis, brucellosis, sarcoidosis and infectious mononucleosis.

CONTRAINDICATIONS

Although the contraindications to needle biopsy of the liver are few, the following represent those to which we have adhered:

1. Uncooperative patient. As emphasized by Sherlock,¹¹ the uncooperative patient is not a suitable candidate for this procedure, since a certain ability and willingness to follow instructions is essential to success. This statement should be construed to include stuporous and comatose patients, as well as children, unless the anterior subcostal approach can be used.

2. A low blood prothrombin content or other evidences of aberrations in the coagulating mechanism. These indicate a real danger of hemorrhage. We have taken a prothrombin concentration of 50 per cent of normal (Quick method) as the minimum below which a biopsy should not be done. As recorded previously, no hemorrhage sufficient to require blood transfusion has occurred in more than 400 biopsies.

3. Infection in the lower lobe of the right lung or right pleural cavity. Biopsy during such infection is inadvisable, because of the possibility of spread to contiguous structures, including the liver.

4. Ascites. Because ascites permits some degree of mobility of the liver, it increases the difficulty of obtaining a satisfactory biopsy specimen, especially in the presence of cirrhosis. For this reason, an abdominal paracentesis should be done before the biopsy is made. Some of the failures to obtain satisfactory specimens in the present series resulted from failure either to observe this precaution or to remove sufficient ascitic fluid at the time of paracentesis.

5. Chronic passive congestion of the liver. Some observers have not hesitated to take a biopsy specimen from a liver congested with blood as the result of cardiac failure. Inasmuch as it would seem that the increased vascular engorgement would make the risk of hemorrhage considerably greater, we have empirically included this condition as a contraindication.

REACTIONS

We have observed the following types of reaction, none of which has proved to be serious:

1. Pain at the site of entry with radiation to the right shoulder. This occurs at the time the biopsy is performed. It is mild and transient and has been noticed by approximately 30 per cent of the patients. A similar reaction occurring after the local anesthesia has dissipated has been observed in a somewhat higher proportion of the patients. This is readily counteracted with codeine and acetylsalicylic acid. It rarely lasts longer than twelve hours and presumably results from local trauma and diaphragmatic irritation.

2. Epigastric discomfort or pain. This is experienced during the time the needle assembly is within the hepatic substance. It is moderately severe on occasion and should be anticipated, since the patient may take a sudden breath if not previously warned.

3. Friction rub. Developing in the region of the biopsy site, this is probably due to fibrinous perihepatitis. The rub is usually of short duration, but in 1 case it persisted for several weeks.

4. Intra-abdominal hemorrhage. This represents the most feared complication, since it was the principal cause of the disasters which have occurred in other series. To date, no serious postbiopsy hemorrhage has been observed in our patients. Close observance for evidences of bleeding should be maintained for twenty-four to forty-eight hours following the biopsy. Blood transfusions may be necessary, and, in the event the hemorrhage continues, operative intervention may be required.

5. Hemorrhage into the pleural cavity or pleural effusion. Penetration of an intercostal vessel or injury to the pleura at the time of penetration may result in hemothorax or transitory pleuritis. Although an effusion was initially attributed to the biopsy in 1 patient in our group, examination at autopsy demonstrated the presence of bilateral effusion resulting from other causes. Injury to the intercostal vessels can be avoided by keeping the needle close to the rib bounding the lower margin of the interspace.

6. Pneumothorax. This was observed in 2 patients. In 1 instance a blunt scalpel blade used in making the incision through the skin penetrated the parietal pleura. The other was associated with pronounced edema of the wall of the chest. In neither instance did the associated pulmonary collapse exceed 10 per cent, nor were there other than mild symptoms.

7. Severe apprehension associated with various nervous and hysterical manifestations. In 1 patient with auricular fibrillation, extreme agitation and impending syncope were observed. There was also an increase in pulse rate. Another patient, who was both agitated and depressed at the prospect of biopsy, developed what appeared to be hysterical apnea lasting approximately ninety seconds. During the apneic period, the pulse rate increased only slightly, blood pressure was maintained and no cardiac lesion could be demonstrated.

11. Sherlock, S.: Aspiration Liver Biopsy: Technique and Diagnostic Application, *Lancet* 2: 397, 1945.

later. The patient had annesia for this period but showed no ill effects.

It should be emphasized, in perusing this list of observed reactions that the majority of patients suffer little or no abnormal response. Although they cannot be said to be eager to have repeated studies, patients do not refuse subsequent biopsies.

Fig. 1 (patient G. C.).—Infectious hepatitis (low power). There is loss of lobular structure with "ballooning" of polygonal cells and focal cellular disintegration evidenced by stromal collapse and lymphocytic clusters. Occasional binucleated cells may be seen.

VALUE OF LIVER BIOPSY

Under the categories listed as indication for liver biopsy, the following cases have been selected to demonstrate the value of the procedure:

Evaluation of Presumptive Hepatomegaly.—R. C. was a well developed, well nourished 8 year old white girl who was found, five months previously, to have hepatomegaly without evident cause or complaint. Four of 5 siblings presented a similar finding. The results of hepatic function tests on all 5 were normal, but 2 of the 5 siblings and the patient had positive reactions to skin tests with histoplasmin. Physical examination revealed slight lymphadenopathy. The liver was palpable 1½ fingerbreadths below the right costal margin. It was smooth, soft and nontender. Results of thymol turbidity, thymol flocculation, cephalin-cholesterol flocculation and serum bilirubin tests were all within normal limits. As no diagnostic abnormalities were recognized in the biopsy specimen, we dismissed the probability of hepatic disease. Our experience with liver biopsy in general has convinced us of the frequency with which a normal liver may be palpable 1 to 2 fingerbreadths below the right costal margin.

Differential Diagnosis of Jaundice.—G. C., a 63 year old white man, was admitted to another hospital because of jaundice. He had had a subtotal gastrectomy five and one-half months previously for gastric ulcer. At the time of operation he received one blood transfusion. One week before his present admission, he noted frontal headache, a "jittery feeling" and dark urine. The following day he observed yellow discoloration of his skin and eyes. Two days before admission diarrhea developed, the stools being whitish. On physical examination, the liver was found to extend 4 fingerbreadths below the right costal margin. It was soft and nontender, save for a tender

nodule on the inferior border in the midclavicular line. Dependent edema (1 plus) was noted. Thymol turbidity of 1 unit was observed, with 3 plus cephalin-cholesterol flocculation in twenty-four and forty-eight hours. Serum alkaline phosphatase measured 13.2 Bodansky units per hundred cubic centimeters. Because of the patient's age, the tender nodule and the increased serum alkaline phosphatase, a diagnosis of jaundice due to neoplasm was made by his physician and the patient was scheduled for exploratory laparotomy. A liver biopsy (fig. 1) revealed the presence of subacute hepatitis, thus averting an unnecessary operation.

H. S., a 54 year old Negro man, was admitted to the hospital with jaundice and an eighteen month history of weakness, intermittent abdominal pain and loss of weight of undetermined amount. The pain had become worse two weeks before admission. Acholic stools and dark urine were said to have been present for one week, and vomiting for three days. The abdomen was slightly distended. The liver extended 5 fingerbreadths below the right costal margin. The gallbladder was not palpable on admission. Thymol turbidity was 2 units. The thymol flocculation test gave negative results. Cephalin-cholesterol flocculation was normal in twenty-four to forty-eight hours; serum alkaline phosphatase was 20.8 Bodansky units per hundred cubic centimeters. Serum bilirubin measured 11.5 mg. prompt and 17.3 mg. total per hundred cubic centimeters. The liver biopsy revealed pronounced bile stasis and acute cholangitis (fig. 2). At operation, a carcinoma of the ampulla of Vater was found. There was no hepatic metastasis.

Diagnosis of Neoplasm of the Liver.—A. R., a 39 year old white woman with a known gastric ulcer, had experienced weakness and fatigue for two weeks before her admission. There were generalized aches and pains with headache, dark urine and moderate pain in the right upper quadrant of the

Fig. 2 (patient H. S.).—Bile stasis (high power). An area adjacent to a central vein showing a large plug of inspissated bile filling an intercellular canal. Polygonal cells here are essentially normal in appearance.

abdomen. For ten years the patient had had intolerance to fatty foods, with bouts of nausea, vomiting and abdominal pain radiating about both costal margins. Jaundice was present. The liver extended 4 fingerbreadths below the right costal margin and was firm and tender. The gallbladder and spleen were not palpable. Thymol turbidity was 2 units. Cephalin-cholesterol flocculation was negative in twenty-four and forty-eight hours. Serum alkaline phosphatase measured 3.4 Bodansky

units per hundred cubic centimeters. On the prompt reaction serum bilirubin was 10 mg. and the total reaction was 12 mg. per hundred cubic centimeters. The patient was thought by some examiners to have infectious hepatitis, possibly of the cholangiolitic type, with antecedent gallbladder disease. In the opinion of others she had a stone in the common duct. Liver biopsy revealed metastatic adenocarcinoma, the primary site of which was not determined.

On occasion one may anticipate considerable difficulty in confirming the presence of hepatic tumor by liver biopsy when the clinical diagnosis appears obvious. In 1 patient with a large nodular liver, the transpleural biopsy specimen showed nothing abnormal. A subsequent needle biopsy was made over a nodule through the anterior subcostal approach. Although four pieces of tissue were removed, evidence of hepatoma was seen in only a small area of one of these fragments.

Determination of the Degree of Progress and the Extent of Hepatic Damage in Cirrhosis.—J. H., a 47 year old white man who had chronic alcoholism, was admitted to the Cincinnati General Hospital in 1942 with hematemesis and ascites. A

was seen to decrease progressively with a hospital diet and rest in bed.

Progress of Hepatitis.—J. D., a 14 year old white girl, experienced fatigue, anorexia and mild nausea ten days before

Fig. 3 (patient J. H.).—Nutritional deficiency cirrhosis (low power). Lobular structure is distorted by narrow, relatively acellular strands of connective tissue. Parenchyma exhibits heavy fatty vacuolization with occasional individual cellular degeneration.

large liver and dilatation of the veins of the abdominal wall were observed. Following his discharge from the hospital, he remained indifferently temperate until two and one-half months prior to his admission in 1947, when he indulged in a prolonged drinking spree, neglecting the while to consume adequate food. Eight days prior to his admission dependent edema and abdominal swelling developed, for which he finally came to the hospital. Physical examination revealed the presence of pectoral alopecia, slight icterus, palmar erythema, numerous spider telangiectases and moderate ascites. The liver was palpated at the level of the umbilicus. Thymol turbidity measured 2 units; thymol flocculation was normal. The cephalin-cholesterol flocculation test showed a 3 plus reaction in twenty-four hours and a 4 plus reaction in forty-eight hours. Serum bilirubin was 1.5 mg. on direct reaction and 2.5 mg. per hundred cubic centimeters on total reaction. Bromsulphalein retention was 29 per cent in forty-five minutes. Three liver biopsies (fig. 4) in a period of seven weeks demonstrated the presence of micronodular cirrhosis, heavy lymphocytic infiltration and fatty vacuolization. The amount of fatty vacuolization

Fig. 4 (patient J. M.).—Fatty infiltration before therapy (low power). The section shows a massive coarse, fatty vacuolization of the parenchyma.

Fig. 5 (patient J. M.).—Fatty infiltration after therapy (low power). Repeat biopsy after ten months of therapy demonstrates notable diminution of the fatty infiltration.

admission. Icteric scleras and mild, dull pain in the epigastric region and right upper quadrant appeared one week before

her admission. Clay-colored stools and dark urine were noted for three days. Physical examination demonstrated the presence of icterus and spider telangiectases. The liver was just palpable below the right costal margin and was tender to both palpation and fist percussion. Thymol turbidity was 12 units; the thymol flocculation test showed a 4 plus reaction. Cephalin-cholesterol flocculation was 3 plus in twenty-four and forty-eight hours. Serum alkaline phosphatase measured 11.6 Bodansky units per hundred cubic centimeters. The first biopsy specimen taken showed little cellular damage, save in the vicinity of the central veins, where a scant lymphocytic reaction obtained. Inflammation of portal islets was particularly prominent, and there was moderate bile stasis confined to the periphery of the lobules. A second biopsy specimen obtained two weeks later revealed the parenchyma to be in the main intact with no bile stasis, in contradistinction to the previous specimen. The portal islets revealed pericholangitis of moderate severity, and in the region of the central vein some disintegration of the hepatic cells was associated with a lymphocytic infiltrate. The third biopsy specimen, procured seven weeks after the onset of the illness, revealed no recognizable abnormality of the hepatic parenchyma. Several portal islets were widened and showed persistence of moderate chronic inflammatory infiltrate. The

TABLE 1.—Changes in Clinical Diagnosis as a Result of Liver Biopsy (51 Cases)

No. of Cases	Clinical Diagnosis	No. of Cases	Diagnosis on Biopsy

persistent portal inflammatory reaction represented continued low grade activity of the hepatitis.

Evaluation of Therapy in Diffuse Hepatic Disease.—J. M., a 55 year old white woman, experienced recurrent episodes of pain and tenderness in the right upper quadrant for twenty-eight years. Cholecystectomy and appendectomy were done in 1935. On physical examination in 1947, the patient was noted to be very obese. The liver was palpable 2 fingerbreadths below the right costal margin and was smooth and nontender. Results of hepatic function tests were within normal limits. A biopsy specimen of the liver (fig. 4) revealed the presence of fatty infiltration. The patient was placed on a regimen including 16 cc. (4 Gm.) of choline¹² dihydrogen citrate N. N. R. daily. A second biopsy specimen obtained three months after the inception of therapy showed no improvement, nor did the third specimen taken three months later. The dosage of choline dihydrogen citrate was increased fourfold, and four months later (fig. 5) there was considerable diminution in the degree of fatty vacuolization.

Recognition of Hepatic Disease.—Table 1 reveals that liver biopsy was of particular value in correcting clinical misconceptions. This was particularly the case in acute hepatitis and portal cirrhosis, and less frequently in obstructive jaundice and intra-abdominal neoplasm. In all, biopsy resulted in a change in diag-

nosis in 51 of 345 cases, or approximately 15 per cent. In 12 miscellaneous cases liver biopsy caused the following changes in clinical opinion:

Biliary cirrhosis to fatty vacuolization—2
Nontropical sprue to metastatic carcinoma
Rheumatoid arthritis to acute hepatitis
Psychoneurosis to portal cirrhosis—2
Chronic passive congestion to portal cirrhosis
Hemochromatosis to portal cirrhosis
"Fatty liver" (with diabetes mellitus) to moderate portal cirrhosis
Chronic glomerulonephritis to portal cirrhosis
Sickle cell anemia to miliary granuloma
Ultimate establishment of sarcoid by lymph node biopsy

Table 2 lists the errors in biopsy diagnosis which have been made in the entire series. As is to be expected, the majority of incorrect diagnoses occurred in the presence of focal lesions which were not included in the biopsy specimen.

There were 16 biopsies reported as failures in our first paper covering 195 biopsies, resulting from lack of adequate material for examination. This figure has now been increased to 24 in a total of 403 biopsies. Although some of the failures occurred early in our experience when only a single attempt at biopsy was made regardless of the adequacy of the material obtained, the most frequent cause of failure was found to be inexperience on the part of the operator. The

TABLE 2.—Errors in Diagnosis on Biopsy (13 Cases)

Case No.	Diagnosis on Biopsy	Final Diagnosis	Comment
16	NDAR* (2 biopsies)	Banti's disease; mild portal cirrhosis	Autopsy (last liver biopsy 6 months before death)
40	Severe bile stasis; acute cholangitis	Carcinoma of head of pancreas, with 3 small hepatic metastases	Autopsy
49	NDAR	Moderate portal cirrhosis	Autopsy
77	NDAR	Banti's disease, with "slight" cirrhosis	Splenectomy with liver biopsy
83	NDAR	Possible Chiari's syndrome; polycythemia vera	Laparotomy with liver biopsy
94	Portal cirrhosis	Portal cirrhosis with hepatoma	Autopsy
98	Severe bile stasis; acute and chronic cholangitis	Carcinoma of the head of pancreas with few small hepatic metastases	Autopsy
133	NDAR	Metastatic carcinoma of liver	Laparotomy; biopsy
171	NDAR	Carcinoma of the stomach with numerous hepatic metastases	Laparotomy with liver biopsy
186	NDAR	Metastatic carcinoma from lung; large and smooth liver, with questionable metastases	No autopsy
199	NDAR	Carcinoma of the stomach, with 3 small hepatic metastases	Autopsy
220	Bile stasis	Carcinoma of the head of pancreas, with numerous hepatic metastases	Autopsy
283	Biliary cirrhosis	Toxic cirrhosis (portal), with recent hepatic infarcts	Autopsy

* NDAR means "no diagnostic abnormalities recognized," with the specimen presumably representing normal liver.

presence of cirrhosis accounted for some of the failures, by reason of the increased consistency of the liver and concomitant ascites. Biopsies made in apprehensive patients occasionally were unsuccessful because of lack of cooperation after the procedure was begun. The attempt was immediately discontinued if the patient

¹² Syrup choline dihydrogen citrate was supplied by Flint, Eaton & Company, Decatur, Ill.

took a breath when told not to do so and no further trials were made. In a few instances, as a result of error in selecting the site of entry, it was evident that hepatic tissue was not being reached when the carrier needle was inserted to its usual depth. A second site was then chosen, treated in the usual manner, and an adequate biopsy specimen obtained without causing undue discomfort to the patient.

It is our opinion that experience with this biopsy technic is now sufficiently large to warrant wider application. Because of the danger of hemorrhage, the procedure should be carried out only by persons who have been trained in centers where this method is extensively employed. It is essential that the pathologist interpreting the biopsy material have great interest in and experience with the method in order to appreciate its advantages and limitations. We believe that the major value of needle biopsy of the liver lies in its simplicity. Although hospitalization is mandatory because of the danger to the patient, confinement need be for only a day or two.

SUMMARY

A method of performing punch biopsies of the liver using the Vim-Silverman needle is described. The indications, contraindications, reactions, failures and examples of cases demonstrating the value of the procedure are given. The safety of needle biopsy of the liver is attested by the absence of any serious reactions in 403 biopsies on 345 patients when the patients were carefully selected and carefully followed.

ABSTRACT OF DISCUSSION

DR. FREDERICK W. HOFFBAUER, Minneapolis: Modern application of the technic of needle biopsy of the liver, stimulated by the studies of Iversen and his associates in 1939, has advanced the clinical study of hepatic disease. Needle biopsy often permits one to establish a definite diagnosis. This is particularly true in certain medical disorders in which the physical findings are not revealing and the biochemical evidences of hepatic dysfunction do not conform to any particular pattern. In the differential diagnosis of the common forms of jaundice, however, needle biopsy of the liver is necessary only in selected cases. The separation of medical from surgical cases can usually be made by clinical and biochemical studies. There are exceptions, but in the main this has been true in my experience.

DR. HANS POPPER, Chicago: The material of Dr. Schiff and his co-workers is, to my knowledge, larger than anyone else's in this country and matches what has been reported by investigators from England and Scandinavia. After sufficient histologic experience has been gained, liver biopsies may provide great help in the differential diagnosis of hepatic diseases. So far, my associates and I have encountered difficulties in histologic differentiation of early hepatic damage produced by extrahepatic biliary obstruction from toxic hepatitis. The flocculation tests did not necessarily help in this situation because, in our experience, they showed nothing abnormal in a not insignificant percentage of cases of toxic hepatitis, similar to surgical jaundice. Following jaundice of two weeks and longer, the histologic differences became clearer and the differentiation between the toxic and the surgical types of hepatitis was far easier; that was usually the time when the question of surgical intervention rendered the differential diagnosis significant. In older cases, little difficulty was encountered in the differentiation of the intrahepatic medical from the extrahepatic surgical biliary obstruction. Study of biopsy specimens of the liver has been intriguing, not only from the practical, diagnostic point of view, but also from the academic point of view of general understanding of hepatic disease. Liver biopsy may facilitate

a classification of the different types of acute hepatic damage. It provides an opportunity to correlate the results of hepatic function tests with morphologic alterations and thus offers an opportunity to evaluate the function tests. Finally, it may improve the rather hazy correlation between clinical picture and pathologic changes of the liver. At present, one is often unable to decide at the autopsy table whether hepatic insufficiency was present or not. Liver biopsy may, therefore, in the future not only enable the pathologist to be of added diagnostic help to the clinician but also permit him to learn more about hepatic disease.

DR. SHEILA SHERLOCK, London, England: My colleagues and I started doing needle biopsies of the liver in 1942; since then we have performed 450 biopsies on 380 patients. Our technic was modified from that of Iversen and Roholm; we, therefore, use a trocar and cannula introduced intercostally. I do not really think there is anything to choose between this method and the use of the Vim-Silverman needle. Provided the biopsy is done after the first week or so, the distinction of obstructive from parenchymatous jaundice is usually clarified by study of the biopsy section. Supplementary evidence for the diagnosis of Hodgkin's disease, the leukemias, sarcoidosis and other such conditions can be obtained by this means. At the Postgraduate Hospital in London we do not perform a splenectomy without preliminary liver biopsy; in this way we save many persons with leukemia, myelosclerosis and hemochromatosis from unnecessary operation. As to mortality, in the first 200 biopsies we had 2 deaths. Since then we have modified our technic and taken more precautions and have had no further fatalities. Recent scrutiny of the literature shows more than 3,000 biopsies on record with 9 deaths. I do not think we ought to regard needle biopsy of the liver as an entirely safe procedure. I doubt that it ever will be, however one modifies it. It is a method one must use in well appointed institutions on carefully selected patients with personal supervision by the physician for twenty-four hours after the puncture and with facilities available for transfusion if necessary. With these provisos, it is a reasonably safe and justifiable procedure.

DR. IRVING B. BRICK, Washington, D. C.: For the past eighteen months my associates and I have done these needle biopsies without sequelae; however, I have noticed gross bleeding through the needle in some cases. Four of every 5 we performed were successful biopsies. I should like to know your average.

DR. LEON SCHIFF, Cincinnati: The Section has been fortunate in having Dr. Hoffbauer, Dr. Popper and Dr. Sherlock discuss our presentation. They are all outstanding in this field and their contributions have been a stimulus in our own studies. In answer to Dr. Brick's question, when we first started doing liver biopsies, our failures were approximately 40 per cent. Our failures now are 5 or 6 per cent, and Dr. Sherlock tells me that her experience coincides with ours. Another means of decreasing the percentage of failures is taking more than one piece of tissue at the time of biopsy. If one fails to obtain a specimen on the first attempt, a second or third attempt should be made at the time of the original biopsy. I might add that, contrary to theoretic expectations, we have noted no increase in frequency of reaction following repeated attempts at biopsy, but that probably is a matter of luck. Is there a "safest" procedure from a technical point of view? Is there a safest approach? I presume the answers to these questions will be forthcoming. One note of caution regarding the anterior approach: I have seen 2 patients who presented what was thought to be a large liver due to the presence of neoplasm. Through blissful ignorance a biopsy specimen was obtained through the transpleural approach, only to find at operation that we were dealing with a tumor of the proximal portion of the transverse colon adherent to the liver instead of neoplasm of the liver! Had we taken the biopsy specimen through the anterior approach, we might have perforated the colon. In regard to the question of bleeding at the site of the incision of the skin, we have done only a few biopsies with the Iversen-Roholm technic; with the Vim-Silverman needle we have noted it on rare occasions.

AUREOMYCIN IN PRIMARY ATYPICAL
PNEUMONIA

A Controlled Evaluation

GORDON MEIKLEJOHN, M.D.
Berkeley, Calif.

and

CAPTAIN ROBERT I. SHRAGG
Medical Corps, Army of the United States

Several reports have already appeared presenting evidence that aureomycin is an effective therapeutic agent in primary atypical pneumonia.¹ All have described the course of the disease in relatively small groups of patients treated with aureomycin. None have presented data on comparable numbers of patients ill during the same period of time who did not receive aureomycin. While the remarkable uniformity of the therapeutic response constitutes a strong argument for the effectiveness of the drug, a certain amount of doubt persists because the course of the disease is exceedingly variable.

Primary atypical pneumonia is exceptionally well suited for controlled evaluation of therapeutic agents. In certain population groups cases may occur in large numbers. The febrile course is long enough in a proportion of the patients to permit the demonstration of a definite shortening of the disease. The fatality rate in young persons is extremely low, making it justifiable to withhold specific therapy from a portion of the patients. No previously available therapeutic agent had been found effective. In view of these considerations, when a suitable opportunity arose, it seemed highly desirable to conduct a study of parallel groups of patients, one of which received aureomycin while the other did not. The present report presents the results of such a study carried out at Fort Ord, California, during the winter of 1948-1949.

MATERIAL AND METHODS

Selection of Patients.—Starting Dec. 5, 1948, all patients with acute respiratory disease admitted to wards at the Station Hospital, Fort Ord, who met all of the following criteria were included in the study group: (a) The clinical course and physical observations suggested that the patient had primary atypical pneumonia rather than bacterial pneumonia²; (b) the roentgenogram of the chest showed unequivocal evidence of pneumonia; (c) the patient's temperature was 102 F., or higher, during the twenty-four hours

prior to institution of treatment; (d) the white blood cell count was less than 12,750, and (e) the patient did not appear to be showing significant improvement. Adherence to these criteria necessitated exclusion of slightly more than half the patients admitted to the hospital during the study period whose course suggested that they had primary atypical pneumonia.

General Plan for Selection of Therapy.—Patients meeting all the criteria outlined were included in the study group. Alternation was accomplished with 30 patients, half of whom received aureomycin and half penicillin. Elimination of certain patients because they failed to meet certain criteria (e. g., roentgen observations were considered equivocal) on occasion disturbed the strict alternation, but the selection remained, as nearly as possible, a random one. In this group of 30, 15 patients on a fixed aureomycin schedule were compared with a similar group on a fixed penicillin schedule.

During the same period 5 additional patients received penicillin shortly after admission to the wards and

TABLE 1.—Comparison of Aureomycin-Treated and Penicillin-Treated Groups Prior to Therapy

Positive observations in roentgenogram of chest.....	18	20
Total number of patients.....	18	20

were subsequently found to meet all criteria for inclusion in the study group. These were balanced in part with 3 similar patients who were given aureomycin, in 2 instances by the intravenous route. Since the inclusion of these patients did not appear to alter the similarity of the groups treated with the two drugs (table 1), results obtained with these 8 patients are presented together with those obtained in the 30 previously described.

A final group of 4 patients consisted of persons who at the start received penicillin and then were given aureomycin. This was done when, after at least forty-eight hours' treatment with penicillin, the patient's condition had obviously become worse and was moderately alarming.

Penicillin was selected for use in the control group for two reasons. First, it was considered desirable to administer some preparation and, prior to the study, penicillin had been generally used in the hope of shortening the course of the disease. Second, it was reasoned that, if patients with bacterial pneumonia were inadvertently included in the series, any therapeutic response obtained with aureomycin would tend to be

This study was carried out under the auspices of the Commission on Influenza, Army Epidemiological Board.

The aureomycin used in this study was supplied by the Lederle Laboratories, American Cyanamid Corporation.

Dr. Meiklejohn is Assistant Professor of Medicine, University of California Medical School, and Consultant in Virology, California State Department of Public Health.

From the Viral and Rickettsial Disease Laboratory, California State Department of Public Health, Berkeley; the Division of Medicine, University of California Medical School, San Francisco; and the Medical Service, Station Hospital, Fort Ord, California.

We received assistance from Dr. E. H. Lennette, Chief, Viral and Rickettsial Disease Laboratory, and Associate Member of the Commission on Influenza; Dr. T. Francis Jr., Chairman, Commission on Influenza; Col. A. L. Gorbey, 6th Army Surgeon, Presidio, San Francisco; Col. J. L. Murchison, Major W. G. Thalmann Jr., Capt. E. Stratton, Capt. A. J. Castagno, Miss Claudine Conway, R.N., Mrs. Phyllis Sands, and other personnel at Fort Ord; and from Col. F. E. Council and Capt. D. L. Weiss at the 6th Army Medical Laboratory, Fort Baker.

canceled out if penicillin were used in the alternate group. This would not be the case if no therapeutic agent were used in the control group. It was our opinion, on the basis of previous experience with penicillin, that the drug was not an effective therapeutic agent in the treatment of primary atypical pneumonia.

Dosage.—Aureomycin therapy was instituted with an intravenous injection of 50 mg. of aureomycin hydrochloride in 5.0 milliliters of a leucine diluent, which contained 131 mg. of L-leucine in 5.0 milliliters, and an oral dose of 1.0 Gm. Thereafter, patients received 1.0 Gm. of drug by mouth every six hours until their temperatures had been normal for at least forty-eight hours. In a number of instances treatment was continued for a longer period. In a small number of cases, when the orally administered drug was poorly tolerated, one or more intravenous injections of 50 mg. of aureomycin were given along with the customary oral doses. At the conclusion of the study a small number of patients were treated on a regimen of 100 mg. intravenously each six hours during the day and a single oral dose of 1.0 Gm. during the night. Penicillin was administered by the intramuscular route in doses of 100,000 units of aqueous penicillin every six hours.

Penicillin.....	3	3	2	3	2	3	4

*Defined as day with oral temperature in excess of 99 F.

Laboratory Procedures.—Complete blood cell counts, urinalysis and roentgenograms of the chest were routine procedures. These were repeated for the most part at weekly intervals. In most patients stained sputum smears were examined, and sputum and blood cultures were taken prior to treatment. The latter were uniformly sterile. It is worthy of comment that bacterial pneumonias were uncommon during this period.

Blood specimens were collected after admission and at weekly intervals thereafter for at least two weeks. Cold agglutination tests were done immediately at the Station Hospital Laboratory. Serums were then shipped to the 6th Army Laboratory at Fort Baker, where agglutination inhibition tests for influenza A and B were performed. Subsequently, complement fixation tests for influenza A and B, psittacosis and Q fever were run at the Viral and Rickettsial Disease Laboratory in Berkeley.

Aureomycin Serum Levels.—Two sets of serum were collected for the determination of aureomycin levels from 7 of the patients treated with aureomycin. The first set was collected one, two, four and six hours after the institution of therapy and the second set forty-eight hours later, when specimens were taken two, four and six hours after an oral dose of 1.0 Gm. Serum was removed from the clot as soon as possible and immediately placed in a carbon dioxide ice chest. Specimens

were stored at temperatures below —45 C. until tested by methods described elsewhere.³

Clinical Study.—All patients were examined by, and followed by, one of us (R. I. S.) as well as by the medical ward officers. Complete records were kept of clinical response and of any evidence of aureomycin toxicity.

Dating the onset of illness caused considerable difficulty, because many persons gave a history of respiratory symptoms, especially cough, from the time of arrival on the post. The date of onset (first day of disease) was interpreted as the day on which symptoms of feverishness or chilliness and exacerbation of previous symptoms were noted.

Patients are identified in the text with one of three prefixes followed by a serial number. Thus, A-1 indicates patient 1 in the aureomycin-treated series; P-1, the same in the penicillin-treated group; and P-A 1, the first in the group started on penicillin and shifted to aureomycin.

Comparability of Aureomycin-Treated and Penicillin-Treated Groups.—Since the validity of any conclusion reached as a result of a controlled study such as this rests on the premise that the two groups are truly comparable, at the conclusion of the study an analysis was made of various factors present at the time of institution of treatment. No significant differences were found with respect to the duration of the disease when treatment with the drug was started, or the maximum temperatures prior to therapy. In the aureomycin-treated group a slightly larger proportion of persons fell in the age group over 20 years, while in the penicillin-treated group a somewhat larger proportion of persons had admission white blood cell counts in excess of 10,000. Roentgen observations defied quantitative analysis, but appeared to be in general similar. A summary of these data is presented in table 1. It was concluded that the two groups were remarkably alike in composition.

RESULTS

Penicillin-Treated Group.—Decided variation in the time required for symptomatic improvement and deferescence was observed in this group of patients. Six of the 20 became afebrile within forty-eight hours after penicillin therapy was started. The febrile courses of the remainder continued for longer periods. In 2 patients fever persisted for as long as twenty-two and twenty-three days, respectively. A summary of the duration of the febrile course is presented in table 2. Symptomatic improvement and clearing of physical and roentgen observations tended to lag behind the drop in temperature. In many instances cough, anorexia and weakness of pronounced degree persisted after the patient became afebrile.

Several patients obviously became worse while receiving penicillin, with rise in temperature, extension of pneumonia and appearance of, or increase in, dyspnea and cyanosis. In 4 of these patients there developed a picture sufficiently alarming to cause discontinuance of penicillin and administration of aureomycin. These patients are discussed in a subsequent section. More frequently, while the patient received penicillin, little

3. Brainerd, H. D.; Bruyn, H. B.; Meiklejohn, G., and Scaparoni, M.: Assay of Aureomycin in Body Fluids: Observation on Individuals Receiving Aureomycin, *Proc. Soc. Exper. Biol. & Med.* **70**: 318-321 (Feb.) 1949.

immediate change was noted in the course of the disease, which dragged on at a somewhat lower level of severity for a considerable number of days.

In summary, while approximately one third of the patients treated with penicillin recovered within forty-eight hours, the courses in the remaining two thirds argue strongly against the drug's being an effective therapeutic agent. In a disease as variable as primary atypical pneumonia a similar distribution has been observed in untreated patients⁴ and might well be observed in any group of patients treated with drugs lacking specific effects. It may be noted that the overall picture in the penicillin-treated group would probably appear even more unfavorable if the 4 most seriously ill patients had not been removed from this group and given aureomycin.

Aureomycin-Treated Group.—In contrast to the penicillin-treated group, all patients treated with aureomycin showed definite symptomatic improvement within three days; in most instances sooner. Twelve of the 18 patients became afebrile within forty-eight hours after therapy was started, and an additional 3 patients within seventy-two hours. Two of the remaining 3 became afebrile within ninety-six hours, and the third was afebrile within one hundred and twenty hours. In other words, 15 of the 18 persons were afebrile within three days after treatment with the drug was begun, and in no instance did fever persist during administration of drug for as long as five days (table 2).

Aureomycin therapy was discontinued in 4 patients between forty-eight and seventy-two hours after the temperature became normal, in 6 between seventy-two and ninety-six hours, in 5 between ninety-six and one hundred and twenty hours and in 2 more than one hundred and twenty hours after defervescence. All patients appeared to be well on the road to recovery when treatment with the drug was stopped, and in 15 of the 18 convalescence continued in an uneventful way. It was the impression of the attending physicians that the clearing of the physical signs and roentgen observations was somewhat more rapid than expected, though these lagged behind the symptomatic improvement of the patient.

The remaining 3 persons (A-11, A-12 and A-15) showed definite evidence of clinical relapse from three to six days after aureomycin therapy was discontinued. Each of the 3 began to have a low grade fever. More important, roentgenograms of the chest, which had in each instance begun to show evidence of clearing, showed evidence of recurrence or extension of the pneumonic area. This suggested a flare-up of the original disease rather than the acquisition of a new disease while the patient was in the ward for disease of the respiratory tract. Two of the patients, because they had white blood cell counts of 15,200 and 29,100, respectively, were given penicillin. Fever persisted until aureomycin was substituted for penicillin. Both these

patients and the third, who had not received penicillin, became afebrile within twenty-four hours after aureomycin therapy was reinstituted. Recovery was uneventful thereafter. A summary of the history of case A-12 is presented as an example of this sequence.

CASE 1 (Fig 1).—Patient A-12, a 17 year old boy, was admitted to the hospital with a hacking cough of ten days' duration. Three days prior to entry the cough had become severer and occasionally productive of bloody sputum and was accompanied with pain under the upper part of the sternum. He had also noted dyspnea on exertion, feverishness, chilly sensations, occasional transitory aches in the legs, slight sore throat, nausea, decided malaise, weakness and watery diarrhea.

On admission, physical examination revealed a slight degree of cyanosis of the lips and nail beds, scattered sibilant rhonchi with dullness and crepitant rales at the left base, and a slightly enlarged left anterior cervical lymph node. The white blood cell count was 6,600. Urinalysis showed a trace of albumin and 4 to 6 white blood cells and 1 granular cast per high power field. Sputum smear and culture showed occasional gram-positive diplococci. No growth was observed in a blood culture.

Fig. 1 (case A-12).—Illustration of relapse at discontinuation of aureomycin therapy.

On the second hospital day, after the temperature had reached 105.8 F. (oral), the patient was given aureomycin, 50 mg. intravenously and 1.0 Gm. orally, followed by 1.0 Gm. orally every six hours. Although the patient vomited about two hours after the first dose, he was able to retain succeeding doses and showed a precipitous drop in temperature within twenty-four hours. However, there ensued persistent vomiting of his medication, so that he was unable to retain any for about twenty-four hours. This was associated with another rise in temperature to a maximum of 103.6 F. (orally) on the morning of the eighth day of illness. Thereafter the temperature fell gradually to normal on the tenth day of disease. Aureomycin determinations on the fifth and seventh days of disease showed serum levels of 5.0 micrograms per milliliter.

Convalescence thereafter progressed satisfactorily, and the aureomycin therapy was discontinued on the twelfth hospital day, after the patient had been afebrile for six days. The patient still complained of weakness with exertion and a slight degree of anorexia, but otherwise had no untoward complaints. Pulmonary observations were minimal and consisted of crackling rales at both bases. Roentgenograms, which had revealed a pneumonic process in the left base on admission, had shown steady and progressive clearing, so that by the fifteenth hospital day only a minimal amount of ragged, increased density in the left cardiophrenic angle was observed.

J.: Clinical and Epidemiological Features of Primary Atypical Pneumonia of Unknown Etiology Among Hospital and Medical School Personnel, *Am. J. M. Sc.* 206: 756-769 (Dec.) 1943. (c) Finland, M.; Peterson, O. L.; Allen, H. E.; Samper, B. E., and Barnes, M. W.: Cold Agglutinins: II. Cold Isohemagglutinins in Primary Atypical Pneumonia of Unknown Etiology, with a Note on the Occurrence of Hemolytic Anemia in These Cases, *J. Clin. Investigation* 24: 458-473 (July) 1945.

Seventy-nine hours after the aureomycin therapy had been discontinued and associated with the patient's first ambulation, there was a recurrence of fever (temperature was 100.6 F., orally) along with increased cough productive of mucopurulent sputum, constricting sensation across lower right side of the chest, malaise, chilliness and slight sore throat.

The white blood cell count on the second day of this febrile episode was 29,100 per cubic millimeter, with 90 per cent polymorphonuclear cells. Smear of the sputum revealed mixed flora with a predominance of organisms resembling streptococci. Culture of the sputum yielded only gram-negative diplococci, and blood culture was subsequently reported as being sterile.

Because of the leukocytosis and high proportion of polymorphonuclear cells in the differential count, it was thought that the patient might be suffering from a bacterial complication. Penicillin, 100,000 units of the aqueous solution, was given every six hours. However, the patient continued to have a low grade fever, associated with aggravation of symptoms and physical signs as well as roentgen evidence of a reinvolvement of the previously clearing left base.

After seven days of penicillin therapy, aureomycin therapy in the dosage previously outlined was reinstituted, with return of the temperature to normal levels in twelve hours. Aureomycin therapy was again discontinued after sixty-eight hours.

Fig. 2. (case P-A 2).—Illustration of initial attack of influenza B followed by primary atypical pneumonia, failure of the patient to improve with penicillin therapy and the prompt response to aureomycin.

Although the physical signs of pulmonary parenchymal involvement were slow in clearing, the patient claimed definite subjective improvement soon after the reinstitution of aureomycin therapy. The cold agglutinin titer was 1:64 on the eighth day of illness and fell off thereafter.

Comment.—This patient's course illustrates exceptionally severe primary atypical pneumonia in which the response to aureomycin, though slow, was satisfactory. Treatment during the first three days was difficult because of repeated vomiting. Despite the fact that aureomycin was continued for five days after the temperature returned to normal, recurrence of fever and evidence of reactivation of the pneumonia occurred within three days after treatment with the drug was stopped. This was accompanied with a leukocyte count of 29,100 with a differential count of 90 per cent polymorphonuclear cells. Fever persisted for seven days while penicillin was given and disappeared within twenty-four hours when aureomycin was given for the second time.

Patients Treated First with Penicillin and Then Aureomycin.—Four patients fell in this group. All had

failed to show evidence of improvement after forty-eight to ninety-six hours of treatment with penicillin and were then given aureomycin because they appeared seriously ill. In each instance decided symptomatic improvement and drop in temperature to normal followed within forty-eight hours after the institution of aureomycin treatment. A résumé of the course of patient P-A 2 is presented as an example of this type of case.

CASE 2 (Fig. 2).—Patient P-A 2, an 18 year old male patient, was admitted with a history of having had a mild nonproductive cough for three weeks. On the day prior to admission he noted increased cough, feverishness, chilly sensations, generalized myalgia, sore throat and intermittent headache and coryza. Results of the physical examination on admission were essentially negative apart from fever (102 F., oral), slight congestion of the palpebral conjunctivas and moderate congestion of the pharynx. The white blood cell count was 5,000.

The patient was treated with symptomatic drugs. On the fourth day of the disease he became afebrile. Complaints of slight coryza, sore throat and cough persisted. Serum specimens collected on the fifth and thirteenth days of disease were tested against influenza A and B viruses, and a diagnosis of influenza B was established by both complement fixation and agglutination inhibition tests.

Five days later the patient's temperature rose sharply to 103 F. There were no complaints, other than the sensation of being feverish, or abnormal physical observations. The white blood cell count had been 9,500 on the previous day. Sputum studies failed to disclose any preponderant organism. The following day the patient suffered from decided malaise, generalized aches and pains, anorexia and recurrence of nonproductive cough. The pharynx was injected, and dulness to percussion was noted over both bases, with occasional crackling rales at the right base. A roentgenogram of the chest on Jan. 13, 1949, revealed a homogeneous density overlying the lateral half of the right hemidiaphragm.

Treatment with aqueous penicillin, in doses of 100,000 units intramuscularly every six hours, was begun. During sixty-six hours on this regimen the patient's condition appeared to become worse, with continued temperature elevations to 103 and 104 F. A second roentgenogram, on January 15, showed infiltrations at both bases. Penicillin therapy was then discontinued and aureomycin therapy started, with 50 mg. given intravenously and 1.0 Gm. orally at the start followed by 1.0 Gm. every six hours. Because of persistent headache and slight meningismus, lumbar puncture was done. Spinal fluid observations were within normal limits. Rapid subjective improvement was noted, and the patient was afebrile within thirty-six hours after aureomycin therapy was started. Convalescence was uneventful.

Comment.—It is of interest that a patient admitted with influenza B became ill with primary atypical pneumonia before discharge from the hospital. The case illustrates well the lack of effect of penicillin in the latter disease and the dramatic response which is often noted with aureomycin therapy.

Comparison of the Course of Aureomycin-Treated and Penicillin-Treated Patients.—Differences between the two groups are brought out most readily by comparison of the duration of the febrile course of one group with that of the other after treatment was begun. For this analysis any oral temperature reading in excess of 99 F. was considered to indicate an active infectious process, since even low grade fever was occasionally associated with recrudescence or a protracted convalescence. When data from the two groups are presented in tabular form (table 2), the difference is striking. The bulk of the aureomycin-treated patients fell in the groups which became afebrile within three

days. In contrast, the majority of the penicillin-treated patients continued to be febrile for three days or more, and 7 of the 20 remained febrile for more than five days. Arithmetic means were not calculated because the excessive duration of the course in a few patients was considered to invalidate any figure obtained in groups as small as these.

TABLE 3.—Maximum Cold Hemagglutinin Titers in Aureomycin-Treated and Penicillin-Treated Groups

Therapy	No. of Pa- tients	Number of Patients with Titers of				
		8 or Less	16	32	64	128 or More
Aureomycin.....	18	6	6	3	2	1
Penicillin.....	20	6	2	1	6	5

Because the type of presentation used herein fails to take into account any difference between a temperature of 99 or 106 F., a more complete record was prepared in the form of miniature temperature charts of each patient before and after treatment (fig. 3). This method has the advantages of showing the course of the disease more accurately and of making clear the time relationship of the response, or lack of response, to the administration of drug. Again the relative uniformity of response with aureomycin is brought out, while the varied response to penicillin is apparent.

Cold Hemagglutination Tests.—In the penicillin-treated group, cold agglutinins were demonstrated in significant titer (32 or more) in serums from 12 of the 20 subjects. In the patients with a more protracted course, a greater proportion of persons had cold agglutinins in significant titer. Thus, only 3 of 9 patients with febrile courses of less than seven days had titers of 32 or more, while 9 of 11 patients with a course longer than eight days had similar titers. This is in line with earlier observations.⁵

TABLE 4.—Aureomycin Serum Levels in 7 Patients

Patient	Aureomycin Serum Level * Following Initial Dose † After				Aureomycin Serum Level * 48 Hours Later ‡		
	1 Hr.	2 Hr.	4 Hr.	6 Hr.	2 Hr.	4 Hr.	6 Hr.

* Micrograms per milliliter.

† The initial dose was 50 mg. given intravenously and 1 Gm. orally.

‡ After 1.0 Gm. given orally.

§ This patient was treated with 100 mg. intravenously for six hours during the day with a single night dose of 1.0 Gm. The drug was not given orally during twelve hours preceding the second series.

The results in the aureomycin-treated patients were somewhat different. Only 6 of the 18 were found to have titers of 32 or more. In the persons with an illness of less than seven days the picture was similar to that of the other group in that 4 of 11 had elevated

titers. However, in the patients with a longer course, only 2 of 7 had titers above 32. There was a further difference between the groups treated with the two drugs in that considerably fewer titers as high as 64 and 128 or more were encountered in the aureomycin-treated group (table 3).

Serologic Tests for Influenza, Psittacosis and Q Fever.—With the exception of 1 patient, P-A 2, significant rises in antibody to these agents were not observed in any subjects.

Leukocyte Response.—In the whole study group (42 patients) there were 6 who showed elevation of total white cell count. These ranged from 17,000 to 29,100, with differential counts showing that the bulk of the increase was due to the polymorphonuclear cells.

Fig. 3.—Comparison of temperature charts of aureomycin-treated group and penicillin-treated group. The shaded area represents the temperature record before treatment, and the black areas after treatment. The arrows indicate the period during which the drug was given.

It will be recalled that white cell counts at the time of admission had in all instances been below 12,750. The leukocytosis occurred during the third and fourth weeks after onset. There was nothing to suggest secondary bacterial infection as a cause of this response. Two of the patients were treated with penicillin during this phase without effect, and then responded promptly to aureomycin. This late leukocytosis has been noted before⁶ and is of practical importance, since it should be realized that, in a patient with pneumonia seen two weeks or more after onset, a high white cell count does not necessarily favor the diagnosis of a bacterial as against a viral pneumonia.

6. Young, Storey and Redmond.¹⁷ Meiklejohn, G.; Eaton, M. D., and van Herick, W.: A Clinical Report on Cases of Primary Atypical Pneumonia Caused by a New Virus, J. Clin. Investigation 24: 241-250 (March) 1945.

Aureomycin Serum Levels.—A summary of the serum levels obtained with two sets of specimens from each of 7 patients is presented in table 4. It will be noted that measurable levels were in all instances present within two hours after treatment was started. The initial 50 mg. intravenous dose, coupled with the oral dose of 1.0 Gm., thus appeared to avoid any appreciable lag in achievement of readable serum levels. While most levels fell between 1.25 and 10.0 micrograms per milliliter, there was considerable individual variation. No data are available which permit any statement regarding levels desirable for therapeutic response. Since a good response was observed in all these patients, and, since others have reported favorable therapeutic responses on smaller dose schedule, it is reasonable to assume that a lower level might be sufficient in primary atypical pneumonia.

Aureomycin Toxicity.—By far the most troublesome manifestation of toxicity due to the drug was the occurrence of nausea and vomiting. This was observed in 9 of the 20 patients who received the drug orally on a schedule of 1.0 Gm. every six hours. A tenth patient had severe nausea without vomiting. With one possible exception (patient A-12) there was no evidence that this interfered with the therapeutic effect. After intravenous administration of the drug no nausea or vomiting was observed. Alteration in the character of the stools, ranging from abnormal bulkiness to watery diarrhea, was observed in 5 patients. In 2 instances the patients appeared abnormally drowsy. It was difficult to ascribe this to the drug rather than to the illness. In 1 patient cheilitis and a smoothness of the tongue were noted four days after aureomycin therapy was begun.

COMMENT

The present study deals with the results of aureomycin therapy in a group of young adults who were suffering from primary atypical pneumonia of more than average severity. In this situation, aureomycin appeared to be uniformly effective in the 22 treated persons. Defervescence was extraordinarily rapid in the majority of patients.

Comparison of these results with those obtained in a control group treated with penicillin brings out two points: first, that a substantial proportion of patients treated with the latter drug recovered soon after institution of therapy; second, that proof of aureomycin effectiveness rests largely on the fact that the protracted type of course observed in a number of the penicillin-treated patients was eliminated. Stated in another way, with patients of the type included in this study, prompt recovery occurred in almost half of the control group. Results with aureomycin could thus be compared only with results in the other half. The actual test of the drug lay in our determining whether, instead of obtaining prompt recovery in only half of the patients, it would be possible to obtain prompt recovery in all. This test appears to have been met.

One point which should be stressed is that relapse apparently may occur in aureomycin-treated patients even when treatment with the drug is continued for several days after the temperature has returned to normal. There was no evidence of reactivation of the disease while patients were receiving the drug, but 3 of the treated patients appeared to relapse after treatment

with the drug was stopped. This is not surprising in view of previous experience with aureomycin in Q fever.⁷ It is reassuring that aureomycin appeared to be as effective in treating the relapse as the initial episode.

The reappearance of cases of primary atypical pneumonia at a military induction center is of some interest. The relatively high incidence of the disease is brought out by the fact that almost one fifth of the patients admitted to the wards for diseases of the respiratory tract during the period of the study were ill with primary atypical pneumonia. The clinical picture was in virtually all respects similar to that observed during epidemics in the early years of World War II.

Cold agglutinins in significant titer were found in substantially the same proportion of patients who were treated with penicillin as in previously studied groups of comparable severity. Agglutinin titers were less frequently above the normal range and tended to be lower in the subjects treated with aureomycin. Since the two groups were similar prior to therapy, it seems not unlikely that treatment with aureomycin suppressed the formation of the cold hemagglutinins. If this proves to be true, the usefulness of the cold agglutination test as a means of confirming the diagnosis of primary atypical pneumonia may be reduced.

A few words might be added in conclusion about the necessary dose of drug and about toxicity. It seems likely that smaller doses may prove adequate. With the oral dosage used in this study, 4.0 Gm. per day, nausea and vomiting occurred with distressing frequency. Both smaller oral dosage and parenteral administration of the drug may offer more satisfactory therapeutic regimens.

SUMMARY

Prompt therapeutic response was observed in 22 patients with primary atypical pneumonia treated with aureomycin. Definite variation in the duration of the disease was observed in a control group of 20 patients treated with penicillin. Comparison of the duration of fever in the two groups indicates that penicillin is not an effective drug and that aureomycin is highly effective in primary atypical pneumonia. Apparent clinical relapse was observed in 3 patients after aureomycin therapy was stopped. Each responded rapidly when treatment with the drug was resumed. Cold agglutinins in significant titer were demonstrated in 12 of 20 patients in the control group and in a smaller proportion of the aureomycin-treated group.

Excessive Deaths in Chicago from Air Pollution.—Based on the low rates prevailing in its clean suburbs, Chicago each year has an excess of 258 deaths from pneumonia among white males in its dirtier districts, 241 from tuberculosis and 69 from buccal and respiratory tract cancers—a total of 568 deaths among white males each year from these three respiratory diseases alone in excess of the death rates these diseases show in the city's cleanest districts. Add to this one-tenth as many deaths for white females and for Negro males, and a grand total is obtained of roughly 700 deaths each year, which represents a measure of the respiratory hazard of living in Chicago's dirtier districts.—Clarence A. Mills and Marjorie Mills-Porter, M.D., *Occupational Medicine*, June 1948, page 633.

D-TUBOCURARINE IN OIL-WAX SUSPENSION
IN RHEUMATOID SPONDYLITIS

Its Use as an Adjuvant

Buffalo

Rheumatoid spondylitis is a chronic progressive disease of unknown causation, involving the sacroiliac joints, the posterior intervertebral (apophyseal) joints, the costovertebral and costochondral junctions and the longitudinal spinal ligaments. This disease is characterized by pain and limited motion of the spine, spasm of the paravertebral muscles, frequent flexion deformity of the spine, limited chest expansion and systemic manifestations of fatigue, loss of weight and strength. Fortunately, proper treatment will relieve the majority of the patients. This treatment consists of roentgen therapy to the spine (which will benefit 90 per cent [plus or minus]), systemic therapy, physical therapy and measures to correct and maintain proper posture (such as spinal brace, postural exercises, bed rest and bed boards). This regimen will relieve pain and prevent deformity in most patients, so that if ankylosis occurs, the spine will be in a position of extension and the chest in full expansion.

The few persons who are not relieved of pain and muscle spasm, and in whom flexion deformity develops, require prolonged, expensive and uncomfortable hospital treatment. Absolute bed rest, firm mattress with bed boards or a Bradford frame and orthopedic measures, such as body casts or skeletal traction, are needed to correct the deformity and produce extension of the spine. One of the most impressive manifestations of the disease in the latter group of patients is the obvious spasm of the paravertebral muscles (extensors of the spine). Since motion is limited in all directions and flexion deformity is frequent, the flexor muscles of the spine are necessarily involved in a similar state of contraction. Consequently, successful treatment of the muscle spasm will be of great benefit to the patient.

Muscle spasm is a state of involuntary muscle contraction which is characterized by pain and resistance to attempted stretching. In rheumatoid spondylitis, it is a reflex protective mechanism to produce splinting and prevent motion of the involved vertebral structures. While it is true that muscle spasm is caused by the pain, we feel that much of the pain (and also the limited motion) is in turn produced by the muscle spasm, thus establishing a vicious cycle of pain. Not only does this cycle become self-perpetuating, but the threshold of the neural arc is lowered and the response becomes abnormally active (stimuli outside the normal range of frequency will elicit muscle response). In an attempt to interrupt this vicious cycle, we have resorted to many measures, among them, intensive physical therapy, procaine hydrochloride injections, neostigmine (prostigmin®) injections and injections of the aqueous solution of curare. Unfortunately, none of these methods have been very efficacious or practical in rheumatoid spondylitis. It is true that the aqueous solution of

curare did produce muscular relaxation, but it was necessary to inject an amount sufficient to produce the unpleasant side effects of curarization (diplopia, generalized muscular weakness, inability to lift the head, difficulty in swallowing and even breathing). Muscular relaxation was transient and persisted only for three to four hours, and maintenance of this level was impractical. However, the preparation of an oil-wax suspension of d-tubocurarine chloride by Schlesinger,¹ which produced prolonged muscular relaxation devoid of the usual side effects of curarization in a group of patients with "acute low back syndromes,"² suggested its use in patients with rheumatoid spondylitis.

The mechanism of muscular relaxation by curare requires some explanation of its action on the myoneural junction. Tubocurarine (the pure crystalline compound isolated from curare) has the ability to block neuromuscular transmission at the junctional region. The exact mechanism of the myoneural junction is still unexplained, but it is probably a combined electrochemical action induced by acetylcholine. Tubocurarine probably acts by interfering with the normal action of acetylcholine on the myoneural membrane or by increasing the threshold for acetylcholine above the available concentration of the drug. Schlesinger³ expressed the opinion that the degree of curare block can be controlled by the concentration of the drug at the myoneural junction. This fact forms the basis of curare therapy—that a partial or critical block can be established which will prevent transmission of abnormal stimuli and thus reduce the abnormal muscle activity (spasm) while normal stimuli will not be blocked and will produce normal muscular contraction. In this manner, muscle spasm can be reduced or abolished without any loss of voluntary muscle response.

This preparation of curare contains 3 per cent d-tubocurarine in a mixture of 4.8 per cent wax in peanut oil (175 units of standard curare per cubic centimeter of suspension). This product has been injected intramuscularly and has resulted in prolonged curare action, lasting from twenty-four hours to more than one hundred and twenty hours in some cases. The dosage has been carefully adjusted, with a low initial dose and increase of the dose gradually at intervals of twenty-four to forty-eight hours until muscular relaxation occurs. Subsequent doses are then administered at whatever interval (usually seventy-two to ninety-six hours) subjective or objective evidence of muscle spasm begins to reappear. Dosage has been an individual problem and is related to the degree of motor acceleration rather than to age or body weight.³ Dosage is lowest in conditions (muscle spasm) where the degree of motor acceleration is the least. As this drug is potentially dangerous (because we are establishing a depot in the body of about twice the normal therapeutic dose of the drug), we have observed certain precautions to prevent toxicity:

1. Begin with a conservative initial dose and increase gradually at intervals of not less than twenty-four hours until muscular relaxation is obtained.

2. Use of dry heat in melting the suspension (and shaking vigorously to insure thorough mixing) and use of dry needle

and syringe in administering the drug, to prevent introduction of moisture into the product.

3. Inject the drug intramuscularly in one site only and do not massage the site of injection.

4. Initial determination of dosage in the hospital where patient's activity can be restricted and observation is possible for eight hours after injection.

5. Discard the product if it shows signs of fluidity or separation at room temperature.

6. Use of this drug is contraindicated when there is evidence of respiratory disease, renal disease, hepatic disease or myasthenia gravis.

If toxicity should result despite these precautions, injection of 1 to 2 cc. of neostigmine (prosgimin®) (1:2,000), which is very effective as a myoneural antagonist, will relieve mild toxic symptoms. In cases of prolonged or serious toxicity (respiratory difficulty), further injection of neostigmine is not beneficial and injections of ephedrine and/or ergotamine tartrate should be administered; an intratracheal airway should be inserted, and artificial respiration and supportive measures should be administered. Ice packs to chill the site of injection will delay further absorption.

Fig. 1 (case 1).—Early rheumatoid spondylitis. A, photograph demonstrating the maximum range of motion before d-tubocurarine therapy. B, photograph showing the increased range of motion after the fourth injection of d-tubocurarine.

However, if the aforementioned precautions are observed, we believe that there will be no serious toxicity. Over two hundred injections were administered to this group of 6 patients with rheumatoid spondylitis, and only two mild reactions (blurring of vision, diplopia) were encountered. No treatment was required.

D-tubocurarine chloride in oil-wax suspension was employed in this group of 6 patients, when the usual treatment regimen for rheumatoid spondylitis (roentgen therapy, physical therapy, spinal supports, bed rest and postural training) failed to relieve their pain, muscle spasm, limited motion and flexion deformity of the spine. Spasm of the extensor (paravertebral) muscles and the muscles of the thighs was an outstanding observation in all 6 patients, and 3 patients had significant spasm of the flexor muscles of the spine. To evaluate the results objectively as well as subjectively, measurements of the range of motion, photographs and electromyographic studies were made before and after administration of d-tubocurarine. The electromyography

measures the electrical activity of the muscle. A normal muscle at rest shows no evidence of electrical activity, but a muscle in spasm exhibits "bursts" of abnormal electrical activity. Needle electrodes were inserted into various muscles, especially the erector spinae group, and in some cases into the muscles of the thigh (hamstring, quadriceps, adductor). After d-tubocurarine administration, the electromyographs showed a decided diminution of the abnormal "bursts" of electrical activity.

Three of the 6 patients treated had relatively early disease (involvement of the lower part of the spine only), 2 patients had moderately advanced disease (involvement of the entire spine, but no ligamentous calcification or ankylosis) and 1 patient had far advanced disease (typical "bamboo" spine, pronounced destructive arthritis of hip joints and a range of only 10 per cent motion of the knee joints). Abstracts of the histories of the 6 patients are reported in order of severity.

REPORT OF CASES

CASE 1.—J. Z., a white boy aged 19, complained of gradually increasing pain and limitation of motion of the lower part of the back for about one year. Previous treatment, consisting of sacroiliac support, roentgen therapy, postural exercises and extensive physical therapy, had not relieved the pain or limited motion of his spine. Physical examination revealed flattening of the normal lumbar curve, loss of 30 per cent motion of the lumbosacral part of the spine in all directions, pronounced spasm of erector spinae and hamstring muscles and considerable pain in the lower part of the back on motion. Roentgenologic examination showed haziness and narrowing of the sacroiliac joints and similar changes in the apophyseal joints of the lower lumbar vertebrae. There was definite evidence of abnormal motor activity on the electromyograph tracings, obtained with needle electrodes in the erector spinae and hamstring muscles. D-tubocurarine was administered, beginning with an initial dose of 0.75 cc. intramuscularly and repeated at twenty-four to forty-eight hour intervals for six doses. After the second injection, the dose was increased to 1.0 cc. (175 units). Following the fourth injection, this patient was able to touch his toes with his finger tips and there was only slight discomfort in the lower part of the back. There was a decided decrease in the degree of muscle spasm at this time. The fifth injection was increased to 1.25 cc., and after this injection the patient complained of blurring of vision, diplopia and a sensation of flushing in the face and head. No treatment was administered since the complaints were very mild. At this time, the patient had a full range of motion of his spine and there was no evidence of muscle spasm either on clinical or electromyographic examination. Dosage was maintained at 1.0 cc. at intervals of four days, for ten more injections. As the patient continued to have a full range of motion of the spine, without pain or muscle spasm, it was decided to discontinue treatment after fifteen injections. At the time of writing this patient had remained asymptomatic for one year with no further treatment.

CASE 2.—R. L., a white man aged 23, had rheumatoid spondylitis involving the sacroiliac joints and the lumbar part of the spine for three years. In the year prior to examination he had noticed a definite increase in pain and a decided impairment of motion of the spine. Examination of the spine revealed the characteristic loss of the normal lumbar curve, loss of 60 per cent of the motion of the lower part of the spine in all directions, moderate decrease in chest expansion and pronounced spasm of the paravertebral muscles and the muscles of the thighs (quadriceps, hamstrings). Roentgenograms showed well advanced arthritic changes in the sacroiliac and all the lumbar apophyseal joints. Electromyographs were obtained of the lumbar paravertebral muscles and the quadriceps group and showed abnormal motor activity. This patient was treated with the usual regimen (which has been described previously),

but experienced only minimal relief of pain and no improvement in the range of motion or the amount of muscle spasm present. After an interval of four months with no change in his symptoms, he was given d-tubocurarine in oil-wax suspension. An initial dose of 0.75 cc. was administered and was increased to 1.25 cc. at forty-eight hour intervals. After the fifth injection there was a definite decrease in the amount of muscle spasm (on clinical and electromyographic study), less pain on motion and a 25 per cent increase in the range of spinal motion. D-tubocurarine therapy was continued in the same dosage (1.25 cc.) at intervals of four to six days until a total of twenty injections was given. At that time, patient had obtained a range of motion 80 per cent of normal and was free of pain and muscle spasm. There was no complaint of toxicity during treatment. At the time of writing he had remained asymptomatic for a year with no other treatment except a Taylor brace.

CASE 3.—A. K., a white man aged 22, had had rheumatoid spondylitis for three years. In the nine months prior to examination, pain in the lower part of the back and left hip had become progressively worse and he had been unable to work. Examination of his spine revealed the lumbar part of the spine to be flat, with loss of 75 per cent normal range of motion, decided impairment of chest expansion, moderately severe pain in the back and left hip region on motion and pronounced spasm of the paravertebral muscles and muscles of the left thigh (quadriceps, adductors). Roentgenograms showed moderately advanced arthritis of the sacroiliac joints, the apophyseal joints of the lumbar part of the spine and mild rheumatoid arthritis of the left hip joint. Since there was little relief of pain, muscle spasm or limited motion after intensive treatment (including bed rest, roentgen therapy, physical therapy and spinal brace), d-tubocurarine therapy was instituted after an interval of three months. The initial dose was 0.5 cc. given intramuscularly; this treatment was repeated at forty-eight hour intervals for four doses. The fifth injection was increased to 0.75 cc. and was given every three days for six doses. At this time, there was a 50 per cent increase in the range of motion of the spine and practically all pain and muscle spasm in the lower part of the back and left thigh were relieved. Injections were repeated at intervals of four to five days for the next five months and then discontinued because he was free of all complaints, except for mild "stiffness and tightness" of the lower part of the back and hip region. This patient received a total of forty-five injections and showed no evidence of tolerance or habituation. The only complaint of toxicity was slight blurring of vision on one occasion, which required no treatment. This patient was able to resume his former occupation after d-tubocurarine therapy was instituted and at the time of reporting had been almost completely asymptomatic for eight months with no treatment except postural exercises and a Taylor brace.

CASE 4.—W. R., a white man aged 41, had had rheumatoid spondylitis for eighteen years. For a year prior to examination there had been a gradual progression of the pain and limited motion of the back and neck and some pain in both hips. Examination revealed decided limitation of motion of the neck and back (20 per cent of normal range of motion), a moderate flexion deformity of the cervical and dorsal parts of the spine and pronounced spasm of the paravertebral muscles of the neck and back. Rotation of both hip joints was limited to 50 per cent, with some pain on rotation and abduction. The quadriceps and adductor muscles of both thighs exhibited a moderate degree of spasm on clinical and electromyographic examination. Roentgenograms showed fusion of both sacroiliac joints, involvement of the intervertebral joints of the entire spine, mild decalcification of the vertebrae and moderate arthritic changes of both hip joints. As this patient had previously been treated with roentgen rays, physical therapy, spinal support and, finally, bed rest, without any improvement of the flexion deformity or muscle spasm and pain, combined neck and leg traction was instituted. Because of the degree of discomfort and the slow progress, traction was discontinued and d-tubocurarine was administered. The initial dose was

0.75 cc. given intramuscularly, and the same dose was given twenty-four hours later. The amount was increased to 1.25 cc. and injection repeated at forty-eight to seventy-two hour intervals. After the fifth injection, it was observed that the patient was able to stand erect and that little spasm of the paravertebral muscles was present. There was little discomfort at this time. Treatment with injections was continued at intervals of three to five days until a total of eighteen doses (1.25 cc.) had been administered. At the conclusion of treatment, this patient was able to stand erect and there was no pain or muscle spasm. There was a moderate increase in the range of motion of the spine (40 per cent normal range of motion). This patient required a Taylor brace, some physical therapy and one subsequent course of roentgen therapy, because of recurrence of a moderate amount of pain, for a period of four weeks. However, at the time of writing there had been no recurrence of the flexion deformity and he had retained

Fig. 2 (case 5).—Moderately advanced rheumatoid spondylitis before treatment. The photographs demonstrate the flexion deformity of the spine, the patient's inability to hold his head erect and the muscle spasm (abdomen).

the improvement in motion. He had been performing his regular occupation, which entailed heavy physical exertion, with minimal discomfort for a year.

CASE 5.—C. H., a white man aged 24, had had rheumatoid spondylitis for five years prior to examination. There had been continuous progression of the disease with involvement of the entire spine, thorax and right hip. There had been increasingly severe pain in the back, neck, chest and right hip; progressive loss of motion of the neck and back; loss of chest expansion, and loss of strength and 40 pounds (18 Kg.) in weight. Examination revealed the dorsolumbar part of the spine to be rigid and decided restriction of all motions of the neck (only 20 per cent normal range of motion of the neck). There was a pronounced flexion deformity of the cervical and dorsal part of the spine and practically no chest expansion. One of the outstanding observations on examination was the

very pronounced spasm of the muscles of the neck, spine, thighs and the abdomen. The electromyograph showed decidedly abnormal motor activity when needle electrodes were inserted into the neck, back and thigh muscles. Roentgenograms revealed typical well advanced involvement of the sacroiliac joints and the entire spine and beginning calcification of the longitudinal spinal ligaments. This patient had been treated several times in the hospital, with an intensive regimen consisting of body casts, traction, physical therapy, roentgen therapy, postural exercises, prolonged bed rest, neostigmine (prostigmin®) and procaine hydrochloride injections, without relief of the pain, muscle spasm or flexion deformity. Treatment with d-tubocurarine in oil and wax was begun with an initial dose of 0.75 cc., which was subsequently increased to 1.25 cc. given at intervals of twenty-four to forty-eight hours. After the

Fig. 3 (case 5).—Photographs of the patient after he had received the seventh injection of d-tubocurarine. They demonstrate the improvement in posture, correction of the flexion deformity of the spine, the patient's ability to hold his head erect and relaxation of abdominal muscles.

fourth injection the patient felt "relaxed" and more comfortable, and after the seventh injection it was noted that he was able to stand more erect and was able for the first time to extend the cervical part of the spine and hold his head erect. Injections were continued at intervals of seventy-two hours for the next month and then were administered every five to seven days for five months, during which time the patient could stand erect with no discomfort and wore a Taylor brace. There had been a 15 per cent increase in the range of motion of the neck and spine. At this time, patient voluntarily discarded his brace and discontinued the injections because he felt well. However, he soon suffered a relapse, with a return of pain, muscle spasm and flexion deformity. He was hospitalized again, and treatment with d-tubocurarine injections was reinstituted, with prompt relief of the pain, muscle spasm and flexion deformity;

an intensive program of physical therapy and muscle-building exercises was started. Improvement was maintained, and the d-tubocurarine therapy was discontinued after he had received a total of sixty injections with no evidence of toxicity or habituation. He required no further therapy, except for the physical therapy, postural exercises and Taylor brace.

CASE 6.—J. A., a white man aged 34, had had a progressive form of rheumatoid spondylitis for twelve years, involving the entire spine, hips, shoulders, thorax and knees, despite all treatment. In 1945, ankylosis of the neck, spine and hip joints was practically complete, and the patient had been confined to bed for the previous two years. Examination revealed a rigid back and neck; no motion in either hip joint could be obtained; severe spasm of the muscles of the back and thighs was present, and any attempt to produce movement of the knee or hip joints was extremely painful. Roentgenograms showed a typical "bamboo" spine and severe arthritis of both hip joints. In the twenty months that he had been hospitalized, the regimen included roentgen therapy, daily physical therapy, prolonged courses of neostigmine (prostigmin®) and procaine hydrochloride injections, with no improvement. He would make an occasional futile attempt to walk with the aid of a walker, but could take only a few steps because of the pain, decided muscle spasm and loss of practically all motion in the hip and knee joints. D-tubocurarine was administered, beginning with 0.75 cc. given intramuscularly, which was subsequently increased to 1.25 cc. at forty-eight hour intervals. After the eighth injection, the patient was able to walk a longer distance, with less discomfort, than for the previous two years. Injections were continued at four to six day intervals for the next four months. The patient continued to improve during this period and was able to walk increasing distances with less discomfort and exhaustion. There was definite evidence of relaxation of the muscles of his back and thighs and an increase of 60 per cent motion of both knee joints during d-tubocurarine therapy. There was only a slight return of motion in the hip joints (15 per cent) and no decrease in the rigidity of the spine. He was able to be out of bed the entire day and was able to walk with little discomfort with the aid of crutches. It was felt by all observers that the rehabilitation of this patient was produced by the d-tubocurarine therapy, as all previous treatment during the hospitalization period of nearly two years had failed to improve his condition in any manner. He received a total of forty-five injections of d-tubocurarine with no evidence of toxicity or habituation and at the time of reporting had maintained this improvement for six months with no subsequent therapy.

COMMENT

D-tubocurarine in oil and wax suspension was administered to a group of 6 patients with rheumatoid spondylitis, after the usual therapeutic regimen for this disease had failed to produce significant improvement. The results of treatment with d-tubocurarine in these patients were: (1) relief of muscle spasm and pain, (2) increased range of motion and strength, (3) correction of flexion deformity of the spine, (4) evidence of diminished abnormal motor activity on electromyographic study after treatment and (5) ability to take more intensive physical therapy and postural exercise. This group of patients received more than two hundred injections of this drug with no evidence of habituation and practically no toxicity. This oil-wax suspension of d-tubocurarine produced a prolonged "curare" effect, lasting up to one hundred and twenty hours in some cases.

SUMMARY

We believe that d-tubocurarine in oil and wax has a definite value as an adjuvant measure in the treatment of rheumatoid spondylitis when the usual regimen of treatment is not successful and when the patient has evidence of significant "muscle spasm."

Council on Pharmacy and Chemistry

ORGANOMERCURIAL COMPOUNDS

A report of the Council, titled "The Bacteriostatic and Bactericidal Actions of Some Mercurial Compounds on Hemolytic Streptococci," by Morton and his co-workers, was published in THE JOURNAL Jan. 3, 1948, page 36. This paper concerned the usefulness of organomercurial compounds, and, in an introductory statement, the Council emphasized that their usefulness should be further explored and defined.

Subsequently, papers by Dr. John H. Brewer and Dr. H. M. Powell on behalf of mercurochrome[®] (merbromin) and merthiolate[®] were published under sponsorship of the Council (THE JOURNAL, July 3, 1948, page 858).

Later the Council considered and commended to THE JOURNAL for publication the paper "Antibacterial Action of Commercial Nitromersol Preparations" by Dr. Hobart W. Cromwell, and the paper "The Action of Blood on Germs Presumably Killed by Antiseptics" by Dr. Lorenzo Banti. These papers and additional comments by the authors have been accepted for publication in the Council column.

The Council is gratified by the prompt response to its challenge for objective evidence of the therapeutic usefulness of the bacteriostatic action of the organomercurial compounds.

In sum, the replies seem to indicate that this bacteriostatic action may, under some conditions, render bacteria noninfective, but that the results vary in conditions that are only partly controllable, especially in clinical practice. It is pointed out that any reduction of infectivity, even though it be uncertain, is to the advantage of the patient, provided (1) that it more than offsets any direct damage to the tissues by the chemical and (2) that the operator appreciate that such reduction of infectivity does not justify any laxness in surgical technic and that asepsis and gentleness must be observed just as meticulously as if no antiseptic were used.

With reference to the paper by Banti, the Council considered that the observation that germicidal action is not merely prevented but actually reversed by blood does not greatly alter the problem, namely, whether the concentrations actually used on and in the body are sufficient to accomplish disinfection without too much toxicity. It is pointed out that this depends on individual conditions that cannot be controlled a priori and that it is still a question of one's giving the patient the benefit of the doubt, provided that the actual success in controlled *in vivo* experiments are sufficient to leave a reasonable doubt.

The Council feels that the papers on this subject published under its auspices do not represent a final answer to its challenge.

AUSTIN SMITH, M.D., Secretary.

ANTIBACTERIAL ACTION OF COMMERCIAL NITROMERSOL PREPARATIONS

HOBART W. CROMWELL, Sc.D.
North Chicago, Ill.

Morton, North and Engley,¹ in a report of their studies of the effect of three mercurials, including nitromersol (metaphen[®]), on pathogenic streptococci, concluded that the aqueous solutions of these mercurials as marketed "possess many shortcomings as disinfectants." This report, with the accompanying comments from the Council on Pharmacy and Chemistry of the American Medical Association, gives the reader the impression that all commercial mercurial preparations are of doubtful value as antibacterial agents. This impression is evident in the semipopular report in *Science News Letter* for Jan. 10, 1948.² Their experiments with nitromersol will be discussed later in this paper.

From the Abbott Research Laboratories.

1. Morton, H. E.; North, L. L., and Engley, E. B., Jr.: The Bacteriostatic and Bactericidal Actions of Some Mercurial Compounds on Hemolytic Streptococci, J. A. M. A. 136: 37-41 (Jan. 3) 1948.

2. *Science News Letter* 53: 29 (Jan. 10) 1948.

The purpose of this communication is to present experimental data on the antibacterial action of two market preparations, metaphen[®] disinfecting solution and tincture of metaphen[®] 1 to 200, which are the nitromersol products most widely used. Metaphen[®] disinfecting solution contains 1 part nitromersol dissolved in 2,500 parts of water containing sodium hydroxide U. S. P., 0.81 Gm.; sodium carbonate, monohydrated, 12.5 Gm.; ethylene glycol, 500 Gm., and benzyl alcohol, 100 Gm. It is recommended for the cold disinfection of dental and surgical instruments. Metaphen[®] tincture, 1 to 200, contains 0.5 Gm. of nitromersol in 100 cc. of an alkalized solvent consisting of alcohol, 50 per cent; acetone, 10 per cent, and water. For preoperative preparation of the skin a certified dye is added to mark the area of application, but for other topical applications the tincture without dye is available.

The experimental data presented here have been selected from studies on mercurial antiseptics made in the Abbott laboratories over the past five years and, therefore, not designed specifically to meet the challenge of the Council. However, the data on metaphen[®] disinfecting solution were accepted in January 1946 by the Council on Pharmacy and Chemistry of the American Medical Association as evidence sufficient to include this preparation in "New and Nonofficial Remedies."

METAPHEN[®] DISINFECTING SOLUTION

Morton and his co-workers,¹ Brewer³ and Powell⁴ have shown that *in vitro* culturing in thioglycollate broth approximates in sensitivity the animal inoculation method of testing viability of mercurial-treated bacteria. In the Abbott tests of metaphen[®] disinfecting solution thioglycollate broth was used for subculture; otherwise the method was the same as described by Ruehle and Brewer.⁵ To 5 cc. of the test solution at 20 C. was added 0.5 cc. of a twenty-four hour culture of the test organism, mixed by shaking. At suitable intervals one 4 mm. loopful of the mixture was planted into 10 cc. of thioglycollate broth and mixed. The cultures were incubated at 37 C. at least four days before final reading of the results.

Table 2 shows the results of sixteen tests of metaphen[®] disinfecting solution against *Staphylococcus aureus*, F.D.A. strain 209, with thioglycollate broth, Linden formula, the same as Morton and his associates used. Complete killing was obtained in all trials in five minutes' exposure at 20 C., and in 13 of the 16 trials no growth was obtained after three minutes' exposure.

In table 1 is the summary of tests against two other strains of *Staphylococcus*, three strains of *Streptococcus*, one strain of *Monilia*, a pathogenic yeast, and two strains of *Escherichia coli*. The broth used for subculture was freshly prepared nutrient broth containing 0.1 per cent sodium thioglycollate. This was used because some of the organisms grew more readily in this than in the Linden formula. Of a total of 128 subcultures made at various time intervals in this series of tests, only two produced growth, one of a *Staphylococcus* after one minute exposure at 20 C. and one of a hemolytic *Streptococcus* after two minutes' exposure.

These results indicate that metaphen[®] disinfecting solution has a definite and rapid lethal action against the organisms tested.

TINCTURE METAPHEN,[®] 1 TO 200

Since tincture metaphen,[®] 1 to 200, is intended primarily for use in preoperative disinfection of skin, it was tested by the in vivo method of Nungester and Kempf,⁶ with a *Pneumococcus* type 1, and a hemolytic *Streptococcus*, strain C 203. In this procedure white

TABLE 1.—Results of Tests of Metaphen[®] Disinfecting Solution Against Various Micro-Organisms at 20 C. with Thioglycollate Broth for Subculture

	Exposure (Minutes)			
	1	2	3	5
Hemolytic streptococcus (2 strains)	1	0	0	0
Positive cultures.....	7	8	8	8
Negative cultures.....	0	1	0	0
Viridans streptococcus (1 strain)	8	7	8	8
Positive cultures.....	0	0	0	0
Negative cultures.....	4	4	4	4
<i>Monilia albicans</i> (1 strain)	0	0	0	0
Positive cultures.....	4	4	4	4
Negative cultures.....	0	0	0	0
<i>Escherichia coli</i> (2 strains)	0	0	0	0
Positive cultures.....	8	8	8	8
Negative cultures.....	0	0	0	0

mice were used as test animals. The tail of the mouse was contaminated with an undiluted blood-broth culture of the organism and, after it was dry, treated with the chemical solution. After a suitable interval, three minutes in these experiments, about 8 mm. of the distal portion of the tail was snipped off and planted in the abdomen of the same mouse. If the mouse survived seven days without visible evidence of infection, the skin was considered "disinfected." Conversely, if the mouse died with morphologically typical organisms in the heart's blood, the skin was not disinfected. Those that died without typical organisms in the blood were very few, and were not included in the summary. The virulence of the test organisms varied somewhat but averaged about 5,000,000 lethal doses per cubic centimeter for 20 Gm. mice for the *Pneumococcus* blood-broth cultures and about 1,000,000 lethal doses per cubic centimeter for the *Streptococcus* cultures.

In table 3 are recorded the results of tests of metaphen[®] tincture in comparison with two competitive mercurial tinctures, M2 and M3, and three tinctures of quaternary ammonium salts, Q1, Q2 and Q3, and the vehicle alone, consisting of alcohol 50 per cent, acetone 10 per cent and water.

None of these preparations was 100 per cent effective, which is not surprising since this test is much severer than would be encountered in the usual operative procedures. The different market preparations varied considerably, which indicates that neither the mercurials nor the quaternary ammonium compounds should be approved or condemned as a class, but that the individual market preparations should be evaluated as nearly as possible for the purpose for which they are intended. Tincture metaphen,[®] 1 to 200, compared favorably with other products tested and was much better than the vehicle consisting of alcohol, acetone and water. With the *Pneumococcus*, it proved effective in 59 per cent of thirty-seven trials and, with *Streptococcus* C 203 in 95 per cent of forty-two trials. The nearest approach to this was a tincture of a quaternary ammonium compound, Q1, which showed 54 per cent

effectiveness against the *Pneumococcus* and 95 per cent against *Streptococcus* C 203. Tincture metaphen[®] was at least equal to the Q1 preparation in skin disinfection and definitely superior to the other commercial preparations.

COMMENT

The Council on Pharmacy and Chemistry of the American Medical Association has invited the manufacturers of mercurial disinfectants to present evidence of the effectiveness of their products. The experimental work of Morton and his associates dealt with aqueous mercurial solutions only, and their results are in agreement with the known characteristics of such substances, namely, their high bacteriostatic potency and slow lethal action against gram-positive organisms. In addition to the usual in vitro disinfectant testing with subcultures in thioglycollate broth, mixtures of the mercurial solutions and organisms were injected into white mice to determine infectivity of the treated bacteria. They found that the equivalent of 100,000 lethal doses of *Streptococcus pyogenes*, strain C 203 M, after ten minutes' exposure of 0.1 cc. of aqueous metaphen,[®] 1 to 500 solution, produced fatal infection in only 3 of 8 mice inoculated. In other words, 100,000 lethal doses were reduced to approximately 1 by this treatment. These results indicate that aqueous metaphen,[®] 1 to 500 solution, does have some merit as a disinfectant, although, admittedly, the authors do not define its field of usefulness.

In common with most known antiseptic chemicals, the activity of metaphen[®] is greatly reduced by contact with tissues and body fluids. A concentration lethal to unprotected organisms in culture might, in the presence of serum, blood or pus, be only bacteriostatic, particularly against gram-positive organisms. Whether

the mixture would be bactericidal, bacteriostatic or entirely ineffective would depend largely on the amount of such organic matter in relation to the concentration of the mercurial. The high bacteriostatic potency should be an advantage in treatment of superficial wounds and abrasions with metaphen,[®] in comparison with other chemicals which are not highly bacteriostatic and which are equally reduced in activity by tissues and body fluids.

6. Nungester, W. J., and Kempf, A. H.: An "Infection-Prevention" Test for the Evaluation of Skin Disinfectants, *J. Infect. Dis.* 71: 174-178 (Sept.-Oct.) 1942.

Aqueous metaphen,[®] 1 to 500, is recommended by the manufacturers only for the irrigation of infected wounds and the preparation of wet dressings, conditions which assure prolonged contact.

The results of Morton's work with aqueous solutions cannot properly be used in estimation of other mercurial preparations containing substances which may have a potentiating effect on the mercurial, or an additive effect, or otherwise may enhance the germicidal properties of the solution. Since metaphen,[®] disinfecting solution and tincture metaphen,[®] 1 to 200, do contain such substances, this experimental evidence of their effectiveness is presented.

Metaphen,[®] disinfecting solution has proved rapidly germicidal against several genera of pathogenic or potentially pathogenic organisms, in tests with subcultures in thioglycollate broth. For this solution, germicidal tests in presence of serum or blood would be unimportant, since the instruments to be disinfected should first be thoroughly cleaned.

Although tincture metaphen,[®] 1 to 200, tested by the rather severe in vivo method of Nungester and Kempf, did not prove 100 per cent effective, it did compare very favorably as a skin disinfectant with five other commercial preparations recommended for that purpose, two tinctures of mercurials and three tinctures of quaternary ammonium salts. It was definitely better than all the others, except possibly one of the quaternary ammonium salts, to which it was at least equal in effectiveness.

SUMMARY

Metaphen,[®] (nitromersol) disinfecting solution has been tested for its germicidal action in vitro against three strains of *Staphylococcus*, three strains of *Streptococcus*, one strain of *Monilia*, a pathogenic yeast, and two strains of *Escherichia coli*, with thioglycollate broth for subculture. By this method the FDA 209 strain of *Staphylococcus aureus* was always killed in five minutes or less at 20 C. in a total of 16 trials. More rapid killing was obtained with the other organisms.

Tincture metaphen,[®] 1 to 200, has been tested for skin disinfection by the in vivo method of Nungester and Kempf in comparison with five other commercial tinctures offered for that purpose, two mercurials and three quaternary ammonium compounds. By this rather severe method, tincture metaphen,[®] 1 to 200, was found definitely superior to all the other preparations, except possibly one of the three quaternary ammonium compounds, to which it was at least equal in value.

The experiments of Morton and his associates on the disinfectant action of aqueous metaphen,[®] 1 to 500, solution, are discussed.

This paper was submitted to Dr. Morton, who, with his associates, wrote the original report and made the following comment:

"The report by Morton, North and Engley (*THE JOURNAL*, Jan. 3, 1948, page 37) dealt only with the aqueous solutions of metaphen,[®] merthiolate[®] and mercurochrome.[®] The replies by Dr. Brewer on mercurochrome[®] and by Dr. Powell on merthiolate[®] (*THE JOURNAL*, July 3, 1948, page 858) likewise, have dealt with aqueous solutions. This report by Dr. Cromwell presents no data on the aqueous solution of metaphen.[®] In a letter to the editor of *The Bulletin of the American Society of Hospital Pharmacists* (that journal, pages 98 and 132, May-June issue, 1948) Edgar B. Carter, Executive Director of Research, Abbott Laboratories, made the statement, 'We have known for many years that, in an aqueous menstruum, a 1-500 dilution of

metaphen[®] is right at the border of the killing range against Gram-positive cocci.' The label on metaphen,[®] 1:500 solution, carries the statement, 'An organic mercury compound of high antiseptic potency. . . .'. Our paper showed that growth of a test organism, after its exposure to a mercurial compound in thioglycollate medium, paralleled infectivity of the organism for the animal body. That has been adequately confirmed. If the micro-organisms are not killed, sepsis may not be prevented.

"Dr. Cromwell in his comments stated that the manufacturers recommend aqueous metaphen,[®] 1 to 500, only for the irrigation of infected wounds and the preparation of wet dressings, conditions which assure prolonged contact. In addition to these, it is also recommended as a first aid measure on the label.

"If the menstruum has a potentiating effect on the mercurial, such action should be demonstrated experimentally and so indicated in descriptive literature (as for example, 'New and Nonofficial Remedies') and on the label, so that users of the compounds do not get the impression that the mercurial, per se, or any other one compound in the product is the sole active ingredient. It is regrettable that Dr. Cromwell did not include in his results in tables 1 and 2 the action of the menstruum in the metaphen[®] disinfecting solution on the test organisms as he did with his work on the action of tincture metaphen[®] listed in table 3."

These comments were submitted to Dr. Cromwell, who replied in part as follows:

"The referees' report makes a point of the omission from this paper of data on the aqueous solution of metaphen.[®] I did not attempt to repeat the work of Morton, North and Engley on aqueous solutions because their experiments seemed to be adequate, and the results in agreement with the known antibacterial characteristics of mercurials, i. e., slow germicidal action against gram-positive organisms, and a powerful and sustained bacteriostatic effect.

"The report implies that the 'use on the package label of the expression 'high antiseptic potency' is an exaggerated description of the antibacterial properties of metaphen,[®] 1 to 500 solution. Possibly the term 'bacteriostatic' is more exact than 'antiseptic,' but, according to my understanding of the term, this solution is antiseptic when used, as recommended by the manufacturer, under conditions assuring prolonged contact.

"With reference to our tests on metaphen[®] disinfecting solution, it did not seem important at the time to test the menstruum alone without the metaphen.[®] Obviously, the menstruum either potentiates the action of the mercurial or has an additive effect, because it has been amply demonstrated that aqueous metaphen[®] solution alone does not kill gram-positive organisms rapidly, while the complete solution proved rapidly germicidal. Benzyl alcohol, 4 per cent solution, is a germicide, and it is listed on the label of metaphen[®] disinfecting solution as one of the active ingredients, although we may not understand completely the mechanism of its action in relation to metaphen[®] in the solution.

"Thank you for giving me the opportunity to read the referees' report and to make these comments."

Dr. Cromwell's comments were referred to Dr. Morton who replied that he had no further comment to offer.

Subsequently the following paper by Lorenzo Banti, Instituto Biologico Argentino, Florencio Varela, F.C.S., Argentina, was received by the Council's office:

THE ACTION OF BLOOD ON GERMS PRESUMABLY KILLED BY ANTISEPTICS

LORENZO BANTI

Florencio Varela, F.C.S., Argentina

A recent report by Morton, North and Engley¹ has opened an interesting controversy about the antibacterial action of some mercurial compounds. Attention has been called by these authors to the fact, already known,² that bacteria believed to be killed, because of their failure to grow in common culture mediums, may be "resuscitated" by being transferred to Linden's thioglycollate broth; they have found, moreover, that hemolytic streptococci susceptible to revival by thioglycollate are also able to infect and cause the death of mice when injected intraperitoneally into them. As the result of these findings the scope of usefulness

of these mercurial compounds as disinfectants would seem to be limited. Brewer³ and Powell⁴ later strove to prove that the mercurials mercurochrome[®] and merthiolate[®] possess, under certain conditions, a definite antibacterial action; but the validity of their conclusions is still open to doubt.

It is already known that germs apparently killed by antiseptics other than mercurials, as phenol, hypochlorites and the like, may be revived by special methods of cultivation. Reference may be made to the papers by Flett, Haring, Guiteras and Shapiro,⁵ Mudge and

Smith,⁶ McIlwain⁷ and Valko and DuBois.⁸ The first of these papers, for instance, shows that ferric chloride or activated charcoal may counteract the effects of the exposure of germs to phenol, although this possibility is limited to concentrations of the antiseptic very little greater than those that are normally considered fatal. It appears that the antiseptic previously bound by the bacterial cells may be removed by chemical or physical action, leaving the germs free from the drug that would ultimately have led to their death. As most tissues and fluids of the animal body contain components chemically similar to components of bacterial cells, it is logical to presume that they will be able to combine similarly with the antiseptics and might even be able to remove the small amounts of them that have been bound by the germs. My co-workers and I thought, therefore, that it would be interesting to investigate this possibility, and we decided to begin by investigating whether, and to what extent, blood might have an effect similar to that of thioglycollate in reviving germs apparently killed by mercurial compounds and, also, whether this action was limited to mercurials or whether it could be observed also with other known antiseptics.

EXPERIMENTAL

The organisms selected for our experiments were twenty-four hour broth cultures of *Staphylococcus aureus*, a germ that is extensively used in performing disinfection tests. For antiseptics we selected: mercuric chloride; two organomercurial compounds, mercurochrome[®] and merthiolate[®]; two chlorine antiseptics, hypochlorite and chloramine T; one quaternary ammonium detergent, octadecyldimethylammonium chloride, and phenol.

As the number of germs used and the amount of organic matter present may alter considerably the results in disinfection tests, we performed two series of experiments. In one of them we added 0.2 cc. of the culture of *Staph. aureus* to 4.8 cc. of the antiseptic solution in each test tube; in the other one we added 1 loopful of the same culture to 5 cc. of the antiseptic solution. At intervals we transferred 1 loopful of the mixture of culture and germicide to each of three tubes containing about 10 cc. of one of the following culture mediums: 2 per cent peptone broth, Linden's fluid thioglycollate medium and blood broth containing 10 per cent fresh defibrinated horse blood in 2 per cent peptone broth. The broth was prepared in both instances by decoction of horse meat 1:2. The three tubes were always inoculated from the same culture-antiseptic mixture tube in the order mentioned, so that the intervals corresponding to the thioglycollate and to blood subcultures were, respectively, about 35" and 70" greater than the interval corresponding to the broth subculture. The growth in the blood broth tubes was not always evident by simple inspection, so that a microscopic control was often necessary; microscopic controls were also generally performed on most of the critical tubes of all mediums.

The hypochlorite solution used was a proprietary product called antibacter[®]; it contained 5.9 parts per thousand of active chlorine.

8. Valko, E. I., and DuBois, A. S.: The Antibacterial Action of Surface Active Cations, *J. Bact.* **47**: 15-25 (Jan.) 1944. The work of Valko and DuBois, however, was not confirmed by Klein, M., and Kardon, Z. B.: The "Reversal," Neutralization, and Selectivity of Germicidal Cationic Detergents, *J. Bact.* **54**: 245-251, 1947.

RESULTS

The results of the first series of experiments are summarized in table 1, those of the second series are summarized in table 2. As most of the experiments were repeated twice, we marked with $\pm$ those that showed growth in one instance and did not in the other one.

Our experiments show that for most of the antiseptics the subcultures in blood broth definitely favor the growth of germs that already fail to grow in peptone broth or even in thioglycollate medium. The thioglycollate medium is possibly more active with mercurial antiseptics than blood broth, as is shown by the results with mercurochrome⁹ in table 2; better results may perhaps be attained with a greater amount of blood. It is to be mentioned that blood broth must be freshly prepared, as it seems to lose some of its properties after a few days.

The germs selected for our experiments did not allow us to check our results by animal inoculation, as was done by Morton, North and Engley, who experimented with a virulent *Streptococcus* strain; but we have been able to show the effect of blood as an antidote on the antibacterial action of most antiseptics. This fact seems to us particularly important, as blood is always present in tissues where an infectious process may develop, so that it will always be available to germs that have not been permanently damaged by the antiseptic.

For mercurochrome⁹ and merthiolate,⁹ under the conditions of our experiments, the bactericidal properties were practically nonexistent when germs exposed to their action were subcultured in blood broth or thioglycollate medium. Even mercuric chloride is shown to be a poor disinfectant. For the remaining drugs the really bactericidal concentrations were mostly found to be higher than might have been expected from the subcultures in peptone broth; but they compare favorably with those that are generally used in practice.

Experiments not recorded here tend to show that serum has also an action similar to defibrinated blood, although it is generally less effective. It is probable that most body tissues exert a more or less similar action.

COMMENT

In 1937 Marshall and Hrenoff⁹ pointed out that the action of an antiseptic may be represented by a graphic, which they called antibacterial spectrum, that shows the properties of a given substance. In this spectrum there is a toxic zone, where the concentration of the antiseptic is too high to be of practical usefulness; a germicidal zone; a bacteriostatic zone, and mostly a zone where, at low concentrations of the drug, it will exert on the germs a stimulating action.

The concentration of the antiseptic is generally considered bacteriostatic when it will prevent the multiplication of the germs, leaving them so far undamaged that they will be able to grow if they are transferred to a medium that does not contain the antiseptic and is able to support their growth. At such concentrations the antiseptic, if harmless, may be used as a preservative.

Bactericidal concentrations are generally much higher, but it is now found that concentrations that would be considered bactericidal if assayed by the phenol coefficient method, that is by the usual method, are not really such in many instances; the germs that

seemed to have been killed may be revived if appropriately treated. Between the bacteriostatic and the bactericidal zone there is a zone, that had scarcely been considered until now, where the action of the antiseptic is reversible. At concentrations corresponding to this zone the germs will absorb enough of the drug to prevent their growth when they are transferred to a medium that would be normally able to support it; but if transferred to a suitable medium the germs will again be able to reproduce. The concept of reversibility seems to me particularly appropriate, as its mechanism appears to be similar to the reversibility of a chemical reaction; there is even here a mass action as the revival of the germs is obtained by the addition of substances capable of combining with the antiseptic; the conditions that had been attained in the culture-antiseptic mixture are reversed when the germs are transferred to a medium that is able to remove and bind the drug that the cells had previously absorbed.

In practice the limits of this reversibility zone may be restricted and distant enough from the toxic zone

TABLE 2.—One Loopful of Culture of *Staph. Aureus* in 5 Cc. of Antiseptic Solution

so as to leave still a margin of safety; the drug will still be useful as a bactericide. But it may happen that the reversibility zone is so wide that it overlaps the toxic zone; the drug will then have no use as a bactericide.

As to the controversy about the usefulness of mercurochrome⁹ and merthiolate,⁹ it seems to me that it cannot be solved if these drugs are considered by themselves, that is without comparison with other known antiseptics. The ideal germicide is probably still to be found; there is still some question about the usefulness of germicides in general; but if a germicide has to be used, one should logically resort to those that show higher germicidal properties and a wider safety margin.

SUMMARY

Blood is able to revive, within certain limits, germs that by ordinary standards would be considered to have been killed by antiseptics. In Marshall and Hrenoff's antibacterial spectrum, between the bacteriostatic and the bactericidal zone, a "reversibility zone" must be inserted, where germs presumably killed may be revived. The extent of this reversibility zone will in part determine the possible usefulness of the drug as a germicide. Mercurial compounds appear, by this standard, to be very poor germicides.

Committee on Cosmetics

The Committee on Cosmetics has authorized publication of the following statement on its rules and procedures. A copy of these rules may be obtained from the Committee office on request.

AUSTIN SMITH, M.D., Secretary.

STATEMENT BY THE COMMITTEE ON COSMETICS

The Board of Trustees of the American Medical Association recently authorized the formation of a Joint Committee on Cosmetics to study problems relating to medical interest in cosmetics and to effect a better understanding of the usefulness of cosmetics. The members appointed are:

Howard T. Behrman, M.D., Assistant Clinical Professor of Dermatology, New York University.

Morris Fishbein, M.D., Editor, JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and *Hygeia*.

Harry R. Foerster, M.D., Assistant Professor of Dermatology, University of Wisconsin; Associate Professor of Dermatology, Marquette University.

Harry Huber, M.D., 122 South Michigan Ave., Chicago.

A. J. Lehman, M.D., Ph.D., Chief, Division of Pharmacology, Food and Drug Administration.

Mr. Herbert R. Mayes, Editor, *Good Housekeeping Magazine*.

Herbert Rattner, M.D., Associate Professor of Dermatology, Northwestern University School of Medicine.

Austin Smith, M.D., Director, Division of Therapy and Research; Secretary, Council on Pharmacy and Chemistry.

Louis C. Zopf, M.D., Professor of Pharmacy; Chief, Department of Drug Service, College of Pharmacy, State University of Iowa.

The first meeting of the Committee was held Oct. 12, 1948, at which time the immediate objectives of the Committee were defined as follows:

1. A study and classification of currently widely used cosmetics.
2. A study of the claims made for these various preparations.
3. The determination of the safety or harmfulness of cosmetic preparations.
4. The preparation of an outline of cosmetics acceptable to the Committee, and of those it now is unwilling to accept.
5. The preparation of a series of informative articles for the medical profession and the general population. (Hair and Scalp Treatments and Preparations, J. A. M. A. 139: 840-844 [March 26] 1949; Hair Dyes, *Hygeia* 27: 318 [May] 1949.)

At a second meeting of the Committee, it was voted that the word "Joint" be dropped from the name of the Committee and that it would be known henceforth as the Committee on Cosmetics and membership increased to include an allergist. At the same time, a seal of acceptance was adopted to be awarded to those cosmetics which meet the requirements of the Committee. In general, the policies in this regard will be similar to other evaluation programs of the Councils in the Division of Therapy and Research.

Manufacturers may now submit their products to the office of the Secretary of the Committee on Cosmetics in conformance with the following official rules.

Official Rules of the Committee on Cosmetics of the American Medical Association

Rules Governing the Acceptance of Cosmetics by the Committee

RULE I—COMPOSITION.—The qualitative and, where possible, the quantitative composition of cosmetics submitted to the Committee must be made known to the Committee. This information will be held in confidence except when it is necessary to reveal the information because of a health problem that arises. Working formulas also will be held in confidence.

RULE II—IDENTIFICATION AND CONTROL.—Suitable procedures for assuring control of the finished product must be supplied to the Committee by the distributor or manufacturer.

RULE III—THERAPEUTIC CLAIMS.—Therapeutic representations normally will not be accepted by the Committee, as such representations normally make the product a drug, which comes within the purview of the Council on Pharmacy and Chemistry. At times, however, there may be exemptions from this rule,

such exemptions being determined individually for the submitted items.

RULE IV—ADVERTISING.—Advertising must conform to claims or statements that can be proved by information submitted by the distributor or manufacturer or that are based on common knowledge.

RULE V—NAMES.—Trademark names for cosmetics accepted by the Committee should not be misleading, suggestive of the treatment of disease or its symptoms or in any way capable of influencing the health of the purchaser by deception.

RULE VI—PATENTS AND TRADEMARKS.—If a cosmetic is patented or trademarked, the number of such patents and the name and number of the registered trademarks should be submitted to the Committee.

RULE VII—USELESS ARTICLES.—A preparation will not be accepted by the Committee if it obviously has no value as a cosmetic.

Outline of Presentation of Submitted Product

When a product is submitted to the Committee on Cosmetics the interested distributor or manufacturer should supply three (3) trade packages of each item; twelve (12) copies of all labels, instructions and advertising material proposed for the product, and a sample of each ingredient contained in the product.

Also accompanying this material there should be a description in triplicate supplying the following:

1. The name of the product, and any synonyms that may be in use.
2. A description of the control procedures that are used to assure a product of the claimed identity, quality and purity.
 - (a) An analysis of each batch of raw materials.
 - (b) An outline of a system for checking the exact amounts of the various ingredients that go into each batch.
 - (c) A description of the record of the lots of raw materials used in each batch.
 - (d) A statement on the code system for identification of each batch.
3. A definition of the article and its complete formula.
4. A description of the physical properties.
5. A statement of any pharmacologic action that might be expected from any of the ingredients and from the final product.
6. A report from qualified experts on the value of the product for those uses for which it is recommended, provided that it differs from those in common use.
7. A report of toxicologic studies, sufficiently complete to establish the safety of the product when put to its intended use.
8. The numbers of any patents and the names and numbers of any trademarks that may have been assigned to the submitted preparations.
9. A list of the forms and sizes in which the article is made available.
10. Studies on patch tests:
 - (a) Two hundred to 1,000 subjects (the figure 200 is to be regarded as an absolute minimum).
 - (b) Method of paired comparisons is desirable, but not required.
 - (c) Control—old formula of similar nature or usage whenever possible.
 - (d) Routine 48 hour test with daily readings for three additional days.
 - (e) Technic: With liquids: Saturate a suitable substance, such as a piece of gauze $\frac{1}{2}$ to 1 inch (1.3 to 2.5 cm.) square, four plies thick; squeeze out excess liquid and apply to normal skin of arm, leg or back; cover with nonwaterproof cellophane 2 inches (5.1 cm.) square and seal with adhesive plaster 3 inches (7.6 cm.) square.

With powder: Place powder on gauze moistened with water or isotonic sodium chloride solution, and duplicate above.

With solids: These can be powdered, or, if soluble, they can be dissolved in definite concentrations and tested as above. When the solid is of a resinous character, the solution containing it may be painted on the skin and the solvent allowed to evaporate. The dry

film of resin can be covered with cellophane and adhesive plaster as indicated.

- (f) Retest in fourteen to twenty-one days following same routine at original sites.

11. Report on usage studies:

- (a) In a controlled group, preferably on the same subjects used in routine patch test studies.
- (b) Duplicate conditions of actual usage and on actual sites of expected usage for a period of from two to twelve weeks.
- (c) It may be advisable to have a control experiment with old cosmetics of similar purpose and/or formula, when claims of superiority are offered or when irritation is a possible factor. Use either on alternate series of subjects or on same subjects dividing body surface (new cosmetics on one side, old cosmetics on other). If no dermatitis occurs in 200 subjects, product is probably safe; if in more than 1, product unsafe. If only 1 case, retest a new series; if 1 or more cases in new series, product is unsafe.
- (d) It may be advisable to have a trial sale, to be carried out where control or supervision can be maintained. Over a six month period, at least one thousand units should be sold and watched. All sales persons should be instructed to report complaints.

12. The name of the firm that is responsible for the finished article as labeled.

13. The names of the manufacturers of all ingredients contained in the article.

14. A statement of the laboratory and control personnel of the firm responsible for the formulation and control of the product.

In some instances it will be unnecessary to supply in detail all data listed in the Outline of Presentation of Submitted Product, if there is sufficient information available in general knowledge pertaining to the products or their ingredients. However, each submitted product must be given individual consideration.

Decisions of General Interest

"Hypoallergenic."—The committee will permit the use of the term "hypoallergenic" when it is applied to products that will meet the Committee's definition for this term. The Committee has defined "hypoallergenic" to mean that every possible care has been taken in formulation and production to insure minimum instance of allergic reaction. In evaluation of products so labeled, the absence from the formula of common allergens and the special selection and purification of ingredients should be the basic criteria. Manufacturers of hypoallergenic products should be prepared to offer clinical data to support the claim.

Definition of "Cosmetic."—For purposes of determining what products come within the purview of the Committee on Cosmetics, a cosmetic has been defined by the Committee as "a preparation which is applied to the skin or its appendages in order to alter its appearance, to protect it, to beautify or to promote attractiveness."

Variation from Standard Formulas.—If a submitted preparation consists of a standard formula (from which minor or insignificant deviations would be permitted) it is unnecessary for the manufacturer to submit data which could be obtained only at considerable expense when it would do nothing except support facts already well known in literature or elsewhere. On the other hand, when new ingredients are included about which there is insufficient information, or when formulas vary in such a way that an entirely new response may occur, it is necessary for the manufacturer or the submitting distributor to supply adequate information to prove the usefulness and safety of the preparation and to defend the claims made for it.

Compliance with Laws.—A declaration by the Committee that submitted formulas and advertising are acceptable merely means that compliance with the Committee's rules has occurred and does not indicate that the copy has been reviewed from the legal standpoint to determine whether it conforms with state and federal laws, this being the responsibility of the interested manufacturer or distributor.

Terms and References Not Recognized.—The Committee will not recognize the use of such terms as "nonallergic," "tissue cream," "hair tonic," "scalp tonic" and "cure." Nor will it recognize a reference to ailments or symptoms of disease, appeals to fear or any other technic whereby the purchaser is misled into accrediting unusual properties or significance to cosmetic products because of stated or implied misrepresentation in advertising material.

The Committee will not recognize disparaging references to competing products. Nor will it recognize references to doctors and hospitals, unless such reference is based on work consisting of controlled scientific data and is offered with full knowledge and consent of all interested parties.

Use of Seal of Acceptance.—Articles that are accepted by the Committee will be eligible for advertising with the Committee seal as long as the claims offered for the products remain acceptable to the Committee.

The Committee seal may not be used for a line of products unless all the products in that line are accepted, nor for a house or organization; the seal must be reserved for products.

The seal or reference to the Committee on Cosmetics should not be used in any way that detracts from their dignity.

Advertising.—Since all advertising for accepted products must conform to the claims recognized by the Committee on Cosmetics, advertising should be forwarded to the office of the Secretary of the Committee, American Medical Association, for review prior to release. Submission of such copy in manuscript form frequently will prevent waste of expensive type or plates when conflicts with recognized claims are discovered.

Council on Physical Medicine and Rehabilitation

REPORT OF THE COUNCIL

The Council on Physical Medicine and Rehabilitation has authorized publication of the following report.

HOWARD A. CARTER, *Secretary.*

COLLINS VITALOMETER ACCEPTABLE

Manufacturer: Warren E. Collins, Inc., 555 Huntington Avenue, Boston 15.

The Collins Vitalometer is a spirometer designed for the determination of vital capacity and related respiratory measurements. It consists of the conventional metal cylinder or bell suspended over water in a slightly larger coaxial cylinder, and properly counterpoised. Readings are made on a dial directly connected with the chain and pulley of the counterpoise system. The height of the bell is 41 cm. (16 inches) and its diameter is 18 cm. (7 inches); its capacity is therefore of the order of 10 liters. The over-all height of the apparatus with the pulley arm telescoped is 61 cm. (24 inches), and with the pulley arm extended it is 86 cm. (34 inches). The apparatus weighs 4.5 Kg. (10 pounds); its shipping weight is 8.2 Kg. (18 pounds). Disposable mouth piece tips are available.

A specimen of the instrument was given a practical trial in connection with a study of spirometry in tuberculosis. No mechanical imperfections were found and the instrument was declared sturdy, practical and accurate within the limits of experimental observation.

The Council on Physical Medicine and Rehabilitation voted to include the Collins Vitalometer in its list of accepted devices.

Collins Vitalometer

SATURDAY, MAY 28, 1949

"PREVENTABLE" ACCIDENTAL AND OTHER DEATHS

Among the many unsupported claims made by the Federal Security Administrator in his promotion of a compulsory health insurance program is the reduction of the number of accidental deaths annually in this country from 100,000 to 60,000, or by 40 per cent. Above the artist's sketch opposite page one of his report to the President ("The Nation's Health—a Ten Year Program") he states: "Goal: Keep them Living—we have the knowledge to prevent 325,000 deaths each year." Thus the Administrator claims that the number of deaths each year can be reduced from the present 1.4 million to 1.1 million, which would be less than the number of deaths in the United States in any year in the twentieth century.

Obviously this reduction cannot be accomplished in an increasing and aging population because the total number dying each year in any nation depends on the number of people, their ages and the death rate per thousand at each age; nor can the annual number of deaths be kept from actually increasing during the coming years. Twenty years ago the number of deaths was one hundred thousand less than last year and life expectancy at birth was seven years less. Twenty years from now the number of deaths in our aging population may well be 1.5 to 1.6 million, the length of life will doubtlessly be greater and the mortality rate for each age will be lower than now. Health progress and the number of deaths each successive year are simply two different ideas. The task of the medical profession over the years is to raise the average age at death, reduce the importance of the "younger" causes of death and increase the importance of the "older" causes of death. Persons who do not die from the younger causes will die later from the older causes. A consideration of the "preventable" 40,000 accidental deaths in this total of "325,000 deaths each year" must not, however, obscure the impossibility of a return to the annual number of deaths which prevailed before 1900.

If the Administrator's estimate of "preventable" accidental deaths is intended as a plea for more and better safety and accident prevention measures, every one will commend the Administrator for bringing an important matter to the attention of the public. Bulletin 64, "What Is the Leading Cause of Death? Two New Measures," by the Bureau of Medical Economic Research of the American Medical Association, has shown that accidental deaths cut off more working years from the lifetimes of the American people than any one natural cause of death. "Fatal accidents" is the number one destroyer of the working years of life. The National Safety Council, the millions of plant safety workers, the traffic policemen and even the school children on patrol duty would doubtless welcome the aid and help of the vast Federal Security Agency in the prevention of accidents. Physicians realize that a comprehensive scheme for an extensive reorganization of the nation's medical services could not eliminate 40 per cent, or 40,000, of the annual 100,000 accidental deaths.

If the accidental death reports published yearly by the Kansas State Board of Health are to be taken as representative of the country as a whole, the proposal is untenable. For 1945, 1946 and 1947, a total of 4,103 fatal accidents occurred in Kansas. Of these, 1,930 deaths, or 47 per cent, occurred instantaneously and 2,468 deaths, or 60 per cent, occurred instantaneously or within one day after the fatal accident.¹ By a strange coincidence the Administrator believes that he can save 40 per cent of lives lost in all fatal accidents. According to the Kansas statistics—the best in the United States on this point—the Administrator apparently proposes to guarantee survival to all who remain alive for twenty-four hours after an accident—or to an equivalent number. The physicians would like to know how compulsory health insurance would save those lives.

CANCERS DUE TO INDUSTRIAL TAR AND ARSENIC

In a recent editorial² on the excessive incidence of cancer of the lung among workers of American chromate plants, attention was called to the increasing significance of industrially important and widely used substances in the causation of cancer in man. Several reports of English investigators discuss the occurrence of cancer of the skin and lung in workers handling inorganic arsenicals² and of cancer of the skin in

1. Nationwide data are available for motor vehicle traffic accident fatalities only for 1945; 59 per cent died within twenty-four hours (Annual Summary of Motor-Vehicle Accident Fatalities, 1945, Vital Statistics—Special Reports, National Office of Vital Statistics, United States Public Health Service, Federal Security Agency, 1947, vol. 27, no. 6).

2. Cancer of the Lung in Chromate Workers, editorial, J. A. M. A. 138: 823 (Nov. 13) 1948.

2. Hill, A. B., and Fanning, E. L.: Studies in the Incidence of Cancer in a Factory Handling Inorganic Compounds of Arsenic, Brit. J. Indus. Med. 5: 1-2, 1948; 1. Mortality Experience in the Factory, ibid. 5: 2-6, 1948. Perry, K.; Bowler, R. G.; Buckell, H. M.; Druett, H. A., and Schilling, R. S. F.: Studies in the Incidence of Cancer in a Factory Handling Inorganic Compounds of Arsenic: II. Clinical and Environmental Investigations, ibid. 5: 6-15, 1948.

workers employed in gas and tar factories.³ The English experience in regard to occupational arsenic and tar cancers is of special interest. Available data provide ample proof as to the carcinogenic properties of tar and arsenic of American manufacture.

An analysis of the cancer mortality, corrected for age and period, among workers of an English factory making arsenical sheep dip showed a notable proportional excess of deaths due to cancer over a period of thirty-five years, as compared with the cancer incidence among farmers, general laborers and artisans and shopowners of the same vicinity. This high factory incidence of cancer among arsenic workers was found to be due solely to a high incidence of cancer of the skin and lung affecting in this occupational group mainly those members engaged in the chemical processes of arsenical manufacture and exposed to the inhalation of and skin contact with arsenical dust. Although the group studied was too small to permit firm conclusions, these epidemiologic observations are in agreement with numerous casuistic reports from various countries. Since there are on record in this country only some 20 cases of cancer due to occupational exposure to arsenic, it seems pertinent to note that in the United States during 1945 the total consumption of white arsenic from domestic and foreign sources amounted to about 38,000,000 short tons. The bulk of the arsenic was used in the production of insecticides (lead arsenate, calcium arsenate, paris green) and of wood preservatives (Wolman salts containing 25 per cent sodium arsenate, zinc metaarsenite). Smaller quantities were employed in the manu-

facture of medicinal preparations, glass, lead base alloys, dyestuffs and chemical warfare gases and in the Thylox purification of industrial gases. Arsenic contained in and deposited on the countryside from the waste fumes of copper smelters and the slag heaps of these operations as well as arsenical insecticides accumulated over a period of years in the soil of orchards and cotton fields have created a potential environmental arsenic hazard not only to the industrially and agriculturally employed population but for the people in general living in such regions. Fruits and vegetables grown in these areas and handled in intrastate and interstate commerce, moreover, carry the hazard to even larger parts of the general population. Since cancers due to arsenic usually have a rather long latent period the etiologic connection between an occupational or environmental exposure to arsenicals and the development of cancer of the skin, lung or other mucous membranes many years later may easily be overlooked.⁴

A similar situation seems to exist in the United States in regard to the recognition and reporting of cancers due to industrial exposure to tar and pitch. There are only some 75 occupational cancers of this causation on record and not a single case of cancer caused by occupational exposure to creosote and anthracene oils. The proper significance of these figures is obtained when they are seen in the light of the following facts:

The total production of gas house and coke oven tar, the most carcinogenic types of tar, stood in 1945 at 696,307,000 gallons, that of creosote oil at 27,000,000 gallons, that of tar acid oil at 13,800,000 gallons, that

THE TRUE PHYSICIAN¹

By Joseph Auslander

Who is the true physician? He
Who feels a sense of ministry;
Who knows our ills are intertwined
With tentacles of heart and mind;
Who knows that man is truly whole
Only when body rhymes with soul;
That the world's sickness will not cease
Till man is with himself at peace.

Who is the true physician? He
Who from despair and fear sets free
Vexed spirit and tormented flesh
Struggling together in the mesh
Of human passions. Undismayed,
He takes the challenge on him laid,
And from facts cruel and uncouth
Creates the cold pure terms of truth.

Physician, you it is to whom
Man's body is a treacherous room
Where day and night and breath by breath
You face infirmity and death,
Confront the furies that by stealth
Slip past the sentinels of health,
And, with no quarter asked or given,
Strive as your gallant dead have striven
To win new ground, and to obtain
Some desperate reprieve from pain,
To fight the valiant fight until
Your faith, your sacrifice, your skill
At first confound, at last confirm
Man's conquest of the Conqueror Worm.

This, true physician, is your story,
Stripped of the accidents of glory,
Beyond all title, all esteem,
Servant of a tremendous dream:
To give man back his right to be
The master of his destiny,
To rescue from the mortal clod
The bright immortal son of God.

1. Poem written for and read at the meeting of the Association of the Alumni of the College of Physicians and Surgeons of the Columbia University in Chicago, June 23, 1948.

3. Jenkins, W. D.: *Dermatoses Among Gas and Tar Workers*, Bristol, John Wright & Sons, Ltd., 1948, p. 54. Ross, P.: *Skin Lesions Due to Pitch and Tar*, Brit. M. J. 2: 369-373, 1948.

4. Hueper, W. C.: *Environmental and Occupational Cancer*, Pub. Health Rep., 1948, supp. 29, p. 69.

of light tar oils at 29,000,000 gallons and that of pitch at 556,000 tons.⁵

Of the English investigators cited, Jenkins found during a ten year period among 234 tar workers 8 epitheliomas and 13 papillomas, among 96 smokeless fuel workers 3 epitheliomas and 13 papillomas, and among 3,006 gas workers 11 epitheliomas and 60 papillomas. Ross, analyzing the incidence of skin cancer among 160 tar and pitch workers during a twelve year period, observed a total of 16 epitheliomas and 102 papillomas. In 87 members of this group the employment period exceeded twelve years. Citing data collected by the Chief Inspector of Factories, Ross noted that there were recorded in England 42 cases of cancer due to tar and pitch in 1922, 97 such cancers in 1930, 119 in 1940, 111 in 1943, 160 in 1944, 176 in 1945 and 201 in 1946.

Since isolated cases of cancer have been reported in American workers engaged in a great number of different industries producing or handling tar, pitch or arsenicals, it appears appropriate that the medical profession pay increased attention to industrial and environmental sources of human cancerigenesis and prepare by prompt and complete reporting of cases of this causation a sound basis for the future control of these preventable types of cancer.

HAZARDS OF BERYLLIUM

Public apprehension concerning the health hazards of fluorescent lights has brought another statement of facts from the Medical Advisory Committee on Beryllium.¹

The committee reiterates its assertion that there is no danger whatever from the lights when they are intact. The possible dangers come in the destruction of old lights. Recently there have been reports of children who cut themselves on broken lights; the cuts healed slowly, and swelling was frequent. Such cuts do not cause general sickness or spread throughout the body. Surgical care is necessary if the cut refuses to heal after a period of time.

Although precautions should be taken against breathing the dust from broken fluorescent lights, records have not been published of any person's suffering injury from breathing dust after the breakage of a lamp.

5. Matthews, A. F., and Bryson, R. L.: Arsenic in Keiser, H. D.: Minerals Yearbook 1945, Washington, D. C., Government Printing Office, 1947, p. 753. DeLarlo, J. A.; Corgan, J. A., and Otero, M. M.: Coke and Byproducts, in Keiser, H. D.: Minerals Yearbook 1945, *ibid.*, 1947, p. 958.

1. The committee includes Dr. James G. Townsend, Chief of the Division of Industrial Hygiene of the Public Health Service, Chairman; Dr. M. G. Carmody, Clifton Products Company, Painesville, Ohio; Dr. T. L. Hazlett, Westinghouse Electric Corporation, Pittsburgh; Dr. J. M. DeNardi, Brush Beryllium Company, Cleveland; Dr. W. H. Machle, New York; Dr. A. D. Nichol, General Electric Company, Nela Park, Cleveland; Dr. A. J. Vorwald, Director, The Edward L. Trudeau Foundation and the Saranac Laboratory, Saranac Lake, N. Y.; Mr. C. R. Williams, Industrial Hygiene Field Service, Liberty Mutual Insurance Company, Boston; Dr. B. S. Wolf, U. S. Atomic Energy Commission, New York, and Dr. Harry Tebrock, Medical Director, Sylvania Electric Products, Inc., Long Island, N. Y.

The safest way to dispose of used fluorescent lights is to break them out of doors in a waste area or in a waste container; the person who breaks them should avoid breathing the dust or vapor that arises.

Possible danger occurs also in the breaking of large numbers of fluorescent lamps, either intermittently or regularly, where hours may be occupied in the operation. Instructions in these cases follow:

(a) Break lamps out of doors in waste disposal area or in ventilated hood. To avoid unnecessary dust, the breakage is best done within the waste container.

(b) The operator should be supplied with, and required to wear, a respirator approved by the United States Bureau of Mines for toxic dusts.

(c) Ultimate disposal of broken lamps should be such that the public and others will not be unduly exposed to powders. In situations where it is necessary to break the lamps within buildings, it should be done in an isolated room and in a hood, so as to minimize escape of dusts. Sufficient exhaust ventilation should be supplied to the hood to provide an air intake of at least 125 linear feet per minute at all hood openings.

Broken lamps should not be placed in an incinerator, but either be thrown into water or in a dump where they are not likely to be disturbed with evolution of dust.

Significant amount of mercury vapor may be found in the air during the breaking of fluorescent lamps. When exposure is frequent or continuous, measurements should be made of the amounts of mercury vapor in the air during the operation. If high levels are found, protection should be provided for the operator.

PROPHYLAXIS OF OPHTHALMIA NEONATORUM

Credé, in 1879, advocated prevention of ophthalmia neonatorum by cleansing the birth canal with 2 per cent phenol solution and placing 1 drop of 2 per cent silver nitrate solution into the eyes of the newborn. The drop in the incidence of ophthalmia, following the adoption of the Credé method, according to Lehrfeld,¹ was due to the attempted cleansing of the birth canal rather than to the instillation of silver nitrate into the eye. Survey of the Department of Public Health records of Philadelphia for fifteen years (1920 to 1935), showed, according to Lehrfeld, that ophthalmia neonatorum has not materially decreased despite the general application of Credé's method.

Lehrfeld found, in an analysis of the records of 28,000 births occurring in six hospitals over a period of five years, that the incidence of ophthalmia neonatorum amounted to 2.2 per cent. Sorsby and his co-workers in England found in a recent survey (1942 to 1944) that the Staphylococcus was most frequently the causative organism, the gonococcus being second in frequency. Lazar stated that in his study 35 per cent of the nongonococcal types of ophthalmia neonatorum showed no micro-organisms of any kind; he assumed

1. Lehrfeld, L.: Limitations of Use of Silver Nitrate in Prevention of Ophthalmia Neonatorum, J. A. M. A. 104: 1468-1469 (April 27) 1935.

that the inflammations were due to chemical irritants such as silver nitrate. Apparently, then, ophthalmia neonatorum is not necessarily synonymous with gonorrheal ophthalmia. McEvoy² examined the records of 236 patients with ophthalmia neonatorum and of 87 with gonococcal conjunctivitis who were not in the newborn age group treated at the Philadelphia General Hospital during the years 1936 to 1947. Lehrfeld interprets this report as indicating that silver nitrate had failed in 236 instances, a conclusion that does not throw light on the true percentage incidence of the condition. McEvoy's comparative study indicates that local application of penicillin into the eyes of the newborn is somewhat superior to treatment with sulfonamide compounds and is much superior to the treatment of gonococcal conjunctivitis with antiseptics of the pre-sulfonamide period. This study does not throw light on the relative merits of the Credé method and the penicillin technic.

Franklin³ used the crystalline salt of penicillin in a concentration of 2,500 units to 1 cc. and, after irrigating the eyes with salt solution, instilled 1 drop of the penicillin solution in each eye, repeating the procedure on the three following days. Gonococcal conjunctivitis did not appear in the group in which penicillin was used, while 1 case occurred on the fourth day in the silver nitrate group, a fact without statistical significance. Franklin concluded that for prophylaxis penicillin compared favorably with silver nitrate and that it was to be preferred because the danger of permanent injury to the eyes was eliminated. Franklin, however, did not present evidence of permanent damage following the use of silver nitrate.

Berens and Foote⁴ expressed the opinion that there will always be cases of ophthalmia neonatorum regardless of the effectiveness of the prophylactic agent. At least two factors may be accountable: carelessness on the part of the attendant instilling the agent and introduction of infection some time after the agent has been instilled. Evidence of permanent damage resulting from the use of 1 or 2 per cent silver nitrate has not been produced. Solutions left standing may reach a concentration as high as 50 per cent. However, supplying 1 per cent silver nitrate in paraffin-lined beeswax ampules, as is done by most health departments, has overcome the danger to the eye from high concentration of the drug.

A subcommittee of the New York Academy of Medicine on Feb. 10, 1948, recommended "that no change be made in the Sanitary Code to require the use of penicillin for the prophylaxis of ophthalmia neonatorum

until there is more experience with its use." On July 20, 1948, the Council of the American Academy of Ophthalmology and Otolaryngology and the Section of Ophthalmology of the American Medical Association approved a report of a joint committee which concluded that the incomplete state of our knowledge on this subject did not justify any change in existing legislation. In full agreement with the conclusions and recommendations of the subcommittee of the New York Academy of Medicine, the group recommended that changes not be recommended now in existing laws, although possibly some form of antibiotic prophylaxis will eventually replace the present use of silver nitrate. Much further investigation of the matter is needed before any concrete recommendations can be made. Such investigations are now in progress in established clinics, and the answers may soon be forthcoming.

NATIONAL SCHOOL HEALTH SERVICES ACT

During the Eightieth Congress considerable effort was made by special groups to secure the enactment of legislation providing for federal aid in the development of school health programs. The legislation then under consideration contained a number of basic deficiencies that prevented the American Medical Association from giving unqualified approval, although the objective has had the endorsement and the active support of the medical profession for many years. The American Medical Association has encouraged periodic examinations of school children at appropriate times during advancement in school and has stimulated the early correction of defects disclosed by such examinations. The Association has collaborated in formulating a school health program now approved by some forty-five different organizations.

A pending bill, S. 1411, to enact a National School Health Services Act, which has passed the Senate, seems scheduled for enactment by the Congress. This bill provides for the general welfare by enabling the several states to make more adequate provision for the health of school children through the development of school health services for the prevention, diagnosis and treatment of physical and mental defects and conditions. Annually \$35,000,000 would be distributed to the states that have developed plans approved by the Federal Security Administrator. The bill also authorizes such other sums as may be necessary for administrative expenses. The beneficiaries of the bill will be the children in public and nonprofit nonpublic schools between the ages of 5 and 17, inclusive—more than 29,000,000 children. A state to be eligible for the federal aid must submit a plan which if it is to be accepted or approved must provide, among other things, (1) for medical and dental examinations at periodic intervals for all school children in the state, such examinations to be made, as far as practicable, at the

2. McEvoy, J. P.: Ophthalmia Neonatorum and Gonococcal Conjunctivitis, *Eye, Ear, Nose & Throat Monthly* 28: 25-29 (Jan.) 1949.

3. Franklin, H. C.: Prophylaxis Against Ophthalmia Neonatorum. Clinical Comparison of Penicillin and Silver Nitrate: Preliminary Report, *J. A. M. A.* 134: 1230-1235 (Aug. 9) 1947.

4. Berens, C., and Foote, F. M.: Penicillin or Silver Nitrate as a Prophylactic Agent Against Ophthalmia Neonatorum? *Am. J. Pub. Health* 38: 1680-1682 (Dec.) 1948.

schools which they attend (this requirement would seem at least to discourage examinations by family physicians) and (2) for treatment of such children for physical and mental defects and conditions disclosed by such examinations, whenever the parents of the children are unable to provide the treatment. However, a state plan may provide for the prevention and treatment of such physical and mental defects and conditions of all school children, irrespective of the financial status of the parents. Too, a state plan must set forth "the manner in which payments are to be made and examinations and treatment provided." Two amendments accepted by the Senate would provide specifically for the utilization of the family physician in providing school health services and would recognize the right of a state to exempt from the program children whose parents are unwilling, on account of religious beliefs, to have the children included in the program.

On a state level, the program will be administered by the state health agency or the state education agency, or both, the decision being left apparently to each state. On a federal level, the Federal Security Administrator is named as the administrative officer. He may delegate at least some of his functions in this respect to other units of the Federal Security Agency. Previous legislation has mentioned the Children's Bureau as the appropriate federal administrative unit, and nothing apparent in the pending bill would prevent the administrator from designating that bureau.

Recognizing that state laws in some jurisdictions may prevent the distribution of funds to provide health service to children attending nonpublic schools, the bill provides that in such cases the Administrator shall withhold from the allotment of such states an amount which bears the same ratio to such allotments as the number of children in average daily attendance at nonpublic schools within the state. With the funds withheld, he will "make provision" for services to children attending the nonpublic schools comparable to the services extended to children attending public schools.

A state plan must further provide for an advisory committee to include representatives of nongovernmental organizations or groups and of state agencies concerned with health, education, child welfare and the interests of the public at large. It must provide that the school health services utilize "and develop" the qualified health, medical, dental, hospital and other related facilities already established in the state. Furthermore, it must contemplate a cooperative arrangement with the medical, dental, health, nursing, psychiatric, educational and welfare groups and organizations, and working agreements, where necessary, with state or local public health agencies having authority under state law for the care of crippled or otherwise physically handicapped children, or for other necessary health services.

The bill does not indicate that a compulsory examination or treatment requirement is contemplated as a prerequisite to school attendance, except possibly as such a requirement obtains under state law. Proper parental consent would no doubt be obtained before any medical procedure on school children under this program is undertaken. This legislation, when enacted, will affect a large segment of our population. Physicians in the several states should interest themselves actively in the formulation of state plans and afterward in their proper and rational administration.

Current Comment

PROFESSIONAL PRINCIPLES AND GOVERNMENTAL CONTROL

The medical profession of the United States has been engaged now for some thirty-five years in opposing the establishment of a federal bureaucracy for the development, control and distribution of medical care. History indicates that medicine not infrequently is the first line of attack by those who favor governmental domination. Once medicine is brought under central management, other professions, industries and trades succumb. A recent issue of the periodical called *The Theatre*, distributed with programs in the theaters of New York City, considers the attempt in connection with consideration of an education bill by the present Congress to provide for the allocation of \$1,000,000 for the establishment of a national theater. Although this idea has been before the theatrical profession for almost ten years, it has now been revived after an abeyance during the last war. Commenting on this subject, Mr. Eugene Burr says:

... though the establishment of a national theatre would unquestionably be an excellent thing, two factors must be borne in mind in any planning. Some way (Thespis alone knows what it could be) would have to be found to guarantee that there would be no bureaucratic domination, that posts in the national theatre would not become political spoils, that the national theatre would be controlled by no exclusive group within the theatre itself. In the second place, jobs in the national theatre would have to be given on the basis of ability rather than need—and this, at least, is a fact whose importance is acknowledged in all of the current plans. A national theatre could not be the means of aiding incompetent amateurs to break into the professional stage. Participants would have to base their claims on ability, not on penury or political affiliation.

But how to establish such standards of ability is a problem; for there can be no absolute standards in any art, but merely evaluations according to individual taste. If somehow someone can solve that problem, without establishing a theatrical clique as the dictator of all standards—and if someone can tell how to guarantee that a national theatre will not become bureaucratic—then a national theatre will be an altogether wonderful thing.

But without those conditions it could become merely a means of disseminating party propaganda, a refuge for political henchmen, an artistic plum for a small group within the theatre itself, or a haven for needy incompetents. And having no national theatre at all is preferable to something like that.

ORGANIZATION SECTION

Official Notes

MORE INTERNS PROTEST NATIONALIZED MEDICINE

The interns of Ancker Hospital, St. Paul, have addressed the following letter to the editor of *The Interne*, a magazine said to be the publication of the interns' organization, protesting unanimsously their disapproval of the platform adopted by the Association of Internes and Medical Students at their convention in 1948 supporting a government-sponsored, national health insurance program. The Association of Internes and Medical Students apparently includes relatively few interns and residents, but claims to represent all:

"We, the internes of Ancker Hospital, St. Paul, Minnesota, have just recently received the February, 1949, issue of *The Interne* containing the report on the AIMS convention of 1948. We were chagrined to note the resolution, stating the AIMS platform in regards to a government-sponsored, national health insurance program, which was 'passed by the panel,' and 'greeted with enthusiasm and endorsed unanimously by the convention.'

"We, the internes of this 700 bed city and county Ancker Hospital, are unanimously opposed to any such government-sponsored program. We are fully cognizant of, and thankful for, the fact that the platform adopted by AIMS is certainly not supported by the vast majority of internes in the United States. We note with pride the advancements made by a free, democratic system of medicine and are confident that such a system will be well able to meet the medical needs of the American people.

Yours truly,
THE INTERNES OF ANCKER HOSPITAL.
[Signed by each intern of Ancker Hospital]

NEW COMMITTEE TO REVIEW HEALTH BILLS

A newly appointed committee, headed by Dr. Harvey Stone of Baltimore, will meet in Washington, D. C., in the near future to review and study all types of health bills introduced in Congress. The committee hopes to coordinate the medical profession's views relating to all legislation.

The bills to be studied will deal with all types of federal regulations as they pertain to medical care, especially the Hill and Taft bills as they relate to public welfare and to the medical profession.

Dr. Elmer Henderson, Louisville, Chairman of the Board of Trustees, and Dr. George Lull, Secretary and General Manager, will serve as ex officio members of the committee; other members are: Drs. R. L. Sensenich, South Bend, President of the American Medical Association; Louis H. Bauer, Hempstead, New York, Chairman of the Executive Committee of the Board of Trustees; R. B. Robins, Camden, Ark.; John W. Cline, San Francisco; Frank Borzell, Philadelphia; Frank Lahey, Boston, and James R. McVay, Kansas City.

COOPERATING WITH COOPERATIVES

The Council on Medical Service of the American Medical Association and representatives of national labor, farm and cooperative organizations representing consumers of medical care met in the Palmer House, Chicago, April 29.

The following joint statement was issued by Dr. James R. McVay of Kansas City, Mo., chairman of the Council on Medical Service, and Jerry Voorhis, executive secretary of the Cooperative Health Federation of America, representing the consumer groups:

"It is the sense of the individuals at this meeting that we are in substantial agreement that voluntary prepayment medical care plans should be developed that will assure the public of the highest quality of medical service and that full assurance

be provided for the maintenance of the quality of good medical care; and that a joint committee be appointed—three by the Council on Medical Service and three by organizations of consumers of medical care—to consider the establishment of standards in conformity with the above principles; and that such committee report back to this assembly at 10 o'clock, Saturday, June 4, in Atlantic City."

Washington Letter

(From a Special Correspondent)

May 23, 1949.

National Health Legislation Witnesses Scheduled

Representatives of more than twenty national organizations will express their views on national health legislation during the first three weeks of Senate committee hearings that were scheduled to open on May 23. Majority of them will be heard during the two week period beginning May 30, since the opening days of the extended hearing were to be devoted to testimony by members of Congress and federal officials supporting the various bills under consideration. These include the Thomas-Murray-Dingell bill calling for compulsory health insurance, the Hill and Taft voluntary assistance measures and the Lodge bill, which provides for "free drugs" to the medically indigent.

The following organizations have been invited to send representatives to testify at the hearings: American Medical Association, American Hospital Association, Congress of Industrial Organizations, Blue Cross Commission, Associated Medical Care Plans, American Federation of Labor, Association of State and Territorial Health Officers, American Public Health Association, Catholic Hospital Association, American Protestant Hospital Association, Americans for Democratic Action, American Dental Association, Cooperative Health Federation of America, Association of Land Grant Colleges and Universities, American Association of Universities, Association of American Medical Colleges, American Council on Education, National Association of State Universities, Association of Schools of Public Health, Association of American Dental Schools, National Association for Practical Nursing, American Nurses Association, National Organization for Public Health Nursing and National League of Nursing Education.

Representative Andersen: "I Pity The People of America"

Representative H. Carl Andersen (Republican, Minnesota) on May 16 delivered a speech on the House floor in which he described socialized medicine as a national calamity if the medical care available at the Capitol to members of Congress is typical of the Truman-Ewing plan. His speech was precipitated by a syndicated newspaper column (Drew Pearson) which stated that the dispensary type of services afforded to members of Congress is essentially socialized medicine.

The Minnesotan said he went to the dispensary with an injured wrist and was advised to soak it in hot epsom salts.

"Fortunately, I had occasion to go to Minnesota three weeks later and, as my wrist was still very painful, contacted my home town doctor who asked me: 'Did you have an x-ray taken of the wrist after the accident?' I answered, 'No, none was suggested.' My doctor in Tyler, Minn., then took an x-ray and found that the wrist had been broken. He said that it was extremely fortunate that the bone had knitted together properly without medical attention.

"All I have to say is that, if the medical service we have available here in the Capitol is a sample of socialized medicine, I certainly pity the people of America if that legislation is enacted into law."

Proprietary Association to Hear Ewing and Dr. Cline

The pros and cons of compulsory health insurance and of the Taft and Hill voluntary assistance plans will be discussed at the sixty-seventh annual convention of the Proprietary Association of America at White Sulphur Springs, W. Va., June 1-3. Speakers will include Federal Security Administrator Oscar R. Ewing, on "The President's Health Program; Its Scope and Objectives"; Dr. John W. Cline, former president of California Medical Association, on "Medicine's Answer to the Truman Proposal for Socialized Medicine," and John W. McPherrin, editor of *American Druggist*, who will report on observations in England while studying its National Health Service system.

To date the Proprietary Association, whose members produce an estimated 80 per cent of the packaged medicines manufactured in the United States, has not taken an official position for or against any of the national health plans pending in Congress. Its headquarters are in Washington. F. J. Cullen, M.D., is executive vice president.

Propagandizing by Federal Security Agency Criticized

Establishment of a Department of Welfare, which would give the present Federal Security Agency cabinet status, was strongly opposed in a House floor speech (May 17) by Representative Clare Hoffman (Republican, Michigan). Such action, he said, would mean surrender "to the bureaucrats in the executive department, in this instance to the Federal Security Agency." He charged the Federal Security Agency Administrator not only with disseminating propaganda but with attempting to justify such activity.

Medical Legislation**STATE LEGISLATION****Delaware**

Bill Vetoed.—S. C. Res. 20, which would have memorialized the Congress of the United States to refrain from imposing on the citizens of this nation any form of compulsory insurance or any system of medical care designed for national bureaucratic control, was vetoed by the Governor on April 28, 1949.

Maine

Bill Enacted.—H. 2076 was approved May 5, 1949. It provides that the use of electrolysis for the removal of hair is not a part of the practice of hairdressing and beauty culture and is prohibited except under the direction of a licensed physician.

Maryland

Bills Enacted.—H. 152 has become chapter 704 of the Laws of 1949. It amends the law relating to the practice of chiropractic by, among other things, providing that a license to practice chiropractic shall not include the right to practice obstetrics. S. 16 has become chapter 669 of the Laws of 1949. It creates an anatomy board to have charge of the distribution of certain dead bodies which come under its control. Such bodies shall be used only for the promotion and application of the medical sciences. S. 329 has become chapter 682 of the Laws of 1949. It amends the law relating to the practice of medicine by providing that applicants for a license who graduated from a college in a foreign country, the entrance requirements, standard of education and requirements for graduation of which are equivalent to the standard defined by the Association of American Medical Colleges or the Intercollegiate Committee of the American Institute of Homeopathy shall be eligible to take the examination for licensure in Maryland.

Michigan

Bills Enacted.—H. Res. 24 was adopted May 9, 1949. It provides for the creation of a special committee to investigate the advisability of establishing a program of rehabilitation for alcoholics. S. C. Res. 19 was adopted May 6, 1949. It memorializes the Congress of the United States not to adopt legislation relative to socialized medicine.

Ohio

Bill Enacted.—H. 308 was approved May 12, 1949. It makes it unlawful to deliver any of the barbiturates except by a pharmacist on the original prescription of a person licensed in the state to prescribe and administer drugs.

Pennsylvania

Bill Enacted.—S. 665 has become Act No. 284 of the Acts of 1949. It provides that certain property to be conveyed to the University of Pittsburgh shall be used for the extension of its Medical Center which will include the Graduate School of Public Health.

Rhode Island

Bills Enacted.—H. 906 was approved May 12, 1949. It provides for the licensing of maternity hospitals. S. 35 was approved May 3, 1949. It creates a special commission to investigate the advisability of establishing facilities for the study, treatment and care of inebriates.

Vermont

Bills Enacted.—H. J. Res. 22 was approved April 26, 1949. It authorizes the governor to appoint a committee composed of a physician and two other persons to make a study of the approximate number of persons in the state suffering from epilepsy and the feasibility of a state program for the care, treatment and rehabilitation of persons so afflicted. H. 139 was approved May 4, 1949. It authorizes the governor to appoint a committee to make a study of the treatment and rehabilitation of alcoholics. H. 338 was approved May 5, 1949. It provides regulations for the licensing of hospitals in the state.

Coming Medical Meetings

American Medical Association, Atlantic City, June 6-10. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Neurology, French Lick, Indiana, French Lick Springs Hotel, June 1-3. Dr. Joe R. Brown, 19 Millard Hall, University of Minnesota, Minneapolis 14, Secretary.

American Academy of Tuberculosis Physicians, Atlantic City, Hotel Dennis, June 4. Dr. Oscar S. Levin, P. O. Box 7011, Denver 6, Colo., Secretary.

American Association of Railway Surgeons, Chicago, Drake Hotel, June 30-July 2. Dr. Chester C. Guy, 5800 Stony Island Ave., Chicago 37, Secretary.

American College of Chest Physicians, Atlantic City, Ambassador Hotel, June 2-5. Mr. Murray Kornfield, 500 N. Dearborn St., Chicago 10, Executive Secretary.

American College of Radiology, Atlantic City, Chalfonte-Haddon Hall, June 5. Mr. William C. Stronach, 20 N. Wacker Drive, Chicago 6, Secretary.

American Dermatological Association, Hot Springs, Va., May 25-28. Dr. Louis A. Brunsting, 102 Second Ave. S.W., Rochester, Minn., Secretary.

American Gastro-Enterological Association, Atlantic City, Claridge Hotel, June 3-4. Dr. Dwight L. Wilbur, 655 Sutter Street, San Francisco 2, Secretary.

American Gastroscopic Society, Atlantic City, Claridge Hotel, June 3-4. Dr. J. Edward Berk, 255 S. 17th St., Philadelphia 3, Secretary.

American Goiter Association, Madison, Wis., Hotel Loraine, May 26-28. Dr. Thomas C. Davison, 478 Peachtree St., N.E., Atlanta 3, Ga., Secretary.

American Medical Women's Association, Atlantic City, June 4-5. Dr. Augusta Webster, 104 S. Michigan Ave., Chicago, Secretary.

American Neurological Association, Atlantic City, Chalfonte-Haddon Hall, June 13-15. Dr. H. Houston Merritt, 710 W. 168th St., New York 32, Secretary.

American Ophthalmological Society, Hot Springs, Va., The Homestead, June 2-4. Dr. Maynard C. Wheeler, 30 W. 59th St., New York, Secretary.

American Proctologic Society, Columbus, Ohio, May 31-June 4. Dr. W. Wendell Green, 1838 Parkwood Ave., Toledo 2, Ohio, Secretary.

American Radium Society, Atlantic City, June 5. Dr. Hugh F. Hare, 605 Commonwealth Ave., Boston 15, Secretary.

American Society for the Study of Sterility, Atlantic City, Hotel Strand, June 5. Dr. Walter W. Williams, 20 Magnolia Terrace, Springfield 8, Mass., Secretary.

American Therapeutic Society, Atlantic City, June 2-5. Dr. Oscar B. Hunter, 915 Nineteenth St. N.W., Washington, D. C., Secretary.

Association for the Study of Internal Secretions, Atlantic City, June 3-4. Dr. Henry H. Turner, 1200 N. Walker St., Oklahoma City 3, Secretary.

Idaho State Medical Association, Sun Valley, June 20-23. Dr. Alfred M. Popma, 220 N. First St., Boise, Secretary.

International Congress on Rheumatic Diseases, New York, Hotel Waldorf-Astoria, May 30-June 3. Dr. Philip S. Hench, Mayo Clinic, Rochester, Minn., Chairman, American Committee.

Maine Medical Association, Poland Spring, Poland Spring House, June 19-21. Dr. Frederick R. Carter, 142 High St., Portland 3, Secretary.

New Hampshire Medical Society, Newcastle, Hotel Wentworth, June 14-15. Dr. Carleton R. Metcalf, 5 S. State St., Concord, Secretary.

Society for Investigative Dermatology, Atlantic City, Ritz Carlton Hotel, June 11-12. Dr. S. William Becker, 55 E. Washington St., Chicago 2, Secretary.

Society of Biological Psychiatry, Atlantic City, Chalfonte-Haddon Hall, June 12. Dr. George N. Thompson, 1136 W. Sixth St., Los Angeles, Secretary.

Western Branch of American Public Health Association, Los Angeles, Hotel Biltmore, May 30-June 1. Mr. Walter S. Mangold, University of California, Berkeley, Calif., Secretary.

GOVERNMENT SERVICES

ARMY

USE OF WACS IN HOSPITALS

While Wacs are already being used in a variety of assignments in Army hospitals, a special effort is to be made to measure the maximum extent to which they can serve in hospital positions traditionally filled by men. The experiment, scheduled to start June 1, will run for one and a half to two years, and they will work both at Murphy General Hospital and at the Lovell Section at nearby Fort Devens.

This experiment will be a guide to determine to what extent enlisted women could be used in hospitals in the event of a national emergency and a consequent man power shortage. They will operate the hospital pharmacy, and will work as photographers, x-ray technicians, mess attendants and stewards, supply clerks and physical reconditioning instructors. Wacs already are filling most of these positions throughout the Army Medical Department, but this is the first time that all such jobs in one hospital will have been filled by enlisted women. A special board of officers, consisting of representatives of the Surgeon General's Office, Women's Army Corps and the hospital staff, will follow the progress of the experiment.

PHYSICAL MEDICINE

A conference on Physical Medicine in Army Hospitals was held April 25-29 in the Surgeon General's Office to review the regulations and policies regarding physical medicine and to propose new regulations in the light of the experiences of two years of physical medicine as a separate service in the Army. Participants included Dr. Frank H. Krusen, director of physical medicine, Mayo Clinic, Rochester, Minn.; Dr. Donald L. Rose, director of physical medicine, University Medical Center, Kansas City, Kan.; Col. Emmett M. Smith, chief, physical medicine service, Walter Reed Hospital; Col. Harold B. Luscombe, M.C., chief, physical medicine service, Fitzsimmons Hospital, Denver; Col. Arthur E. White, M.C., chief, physical medicine service, Letterman Hospital, San Francisco, and Capt. E. J. Lorenze, M.C., acting chief, physical medicine consultants division, Surgeon General's Office.

AIR FORCE

ARCTIC AEROMEDICAL LABORATORY

The Air Force Arctic Aeromedical Laboratory has completed its second winter of operations at Fairbanks, Alaska. The laboratory is attempting to collect physiologic, biochemical and psychologic data on the difficulties of living in the Arctic. Preliminary biochemical investigations conducted at the Arctic Laboratory demonstrated that blood coagulation times are prolonged under Arctic conditions, and current studies are aimed at determining the stage of the clotting process that is involved. Animal studies are in progress to determine the reasons for the greater tolerance of some species for Arctic cold than others.

Colonel Jack Bollerud, head of the Laboratory, states that living under conditions of Arctic weather and isolation carries with it a serious morale problem. Men sent to Ladd Field accordingly are being given standard psychologic tests on arrival and monthly for one year in an attempt to fathom the factors involved. It is expected that personality responses and changes thus determined will aid in the development of psychologic selection techniques for Arctic duty.

During the relatively mild Alaskan summer, the base line psychologic program is continued, but most of the cold weather

OFFICERS SELECTED FOR ADVANCED TRAINING

The following medical officers have been selected for advanced training in the civilian schools and hospitals indicated:

Officer	Institution	Subject
Raymond E. Duke, Col.	University of Minnesota, Minneapolis	Public Health
Benjamin H. Sullivan Jr., Col.	American College of Physicians, Philadelphia	Cardiovascular disease
Arthur E. H. Knox, First Lieut.	St. Luke's Hospital, New York	Medicine
Walter F. Reeves, First Lieut.	Indiana University Medical Center, Indianapolis	Intern training
Lester J. Nienhuis, First Lieut.	University Hospital, Ann Arbor, Mich.	Residency in general surgery
George W. Pogson, First Lieut.	Kansas City General Hospital, Kansas City, Mo.	Residency in internal medicine
Franklin M. Lockwood, First Lieut.	Kansas City General Hospital, Kansas City, Mo.	Residency in surgery
Irvin L. Schweitzer, First Lieut.	Mercy Hospital, Chicago	Residency in medicine
Harry J. Umlauf Jr., First Lieut.	Children's Hospital Society, Los Angeles	Residency in pediatrics
Arthur J. Moseley, First Lieut.	Grady Memorial Hospital, Atlanta, Ga.	Residency in medicine
Max W. Pegram, First Lieut.	Hospital of St. Barnabas, Newark, N. J.	Residency in plastic surgery
Kent T. Woodward, First Lieut.	Georgetown University Hospital, Washington, D. C.	Residency in medicine
Dean F. Winn Jr., First Lieut.	San Francisco Hospital, San Francisco, Calif.	Residency in surgery
William W. Tucker, First Lieut.	St. Luke's Hospital, San Francisco, Calif.	Residency in surgery
William W. Thompson, First Lieut.	Duke Hospital, Durham, N. C.	Residency in pediatrics
Edwin E. Pontius, First Lieut.	Indiana University Medical Center, Indianapolis	Residency in clinical pathology and pathology
Joseph A. Roy, First Lieut.	De Paul Hospital, St. Louis	Residency in surgery
Hugo M. Cardullo, First Lieut.	Bellevue Hospital, New York	Residency in pediatrics

research is suspended. Newly arrived personnel are being trained for their role in the active winter program for the year ahead.

INITIATE GENERAL PRACTICE BRANCH

Major General Malcolm C. Grow, the Air Surgeon, announces the initiation of a general practice branch in the Air Surgeon's office, to be charged with the development of training opportunities and careers for general practitioners serving at Air Force installations. According to current Air Force organization, about 70 per cent of physicians serving with Air Force units are general practitioners. Of the remainder, 5 per cent are staff and administrative personnel and 25 per cent are specialists. General Grow characterized the general practitioner as "the backbone of the Air Force medical service." Under the new program the general practitioner will be enabled to enter into a proposed residency program to be operated in the general hospital setup. The residency program will offer the general practitioner access to latest technical developments in medical and surgical specialties. Emphasis will be placed on internal medicine, surgical practices, pediatrics and obstetrics. The new general practice branch will work cooperatively with the Surgeon General's career program for medical officers.

VETERANS ADMINISTRATION

ELIMINATE THIRTEEN BRANCH OFFICES

The Veterans Administrator announces the selection of five key points from which medical supervision of hospitals and other medical matters will be carried on. They are Atlanta, Boston, Fort Snelling, Minn., San Francisco and St. Louis. The plan for medical supervision from these points resulted from the elimination of the thirteen branch offices of the Veterans Administration where medical activities previously were under the direction of branch medical directors. All functions of former branch office medical staffs are now centered in the office of the Chief Medical Director in Washington. The Administrator said, "In connection with medical matters handled in Washington, it is necessary that we have representatives traveling throughout the country. For the sake of reduced travel expense and other economies, certain Central Office representatives will be stationed at strategic points, to serve as the eyes and ears of the Chief Medical Director." He emphasized that "in no sense will these official stations become operating offices. They will simply be points from which Central Office personnel will travel. This change will bring supervision of the Chief Medical Director closer to hospital and other medical activities in the field, thereby assuring maintenance of the finest medical service to veterans."

RESIDENCIES IN NEUROLOGY

Several openings are available in the residency training program in neurology at the Veterans Administration Hospital, Coatesville, Pa. The program, organized by the Philadelphia Deans Committee, has been approved by the American Medical Association. This residency covers a period of three years or less, depending on the previous experience of an applicant, and is designed to prepare residents for certification in neurology by the American Board of Psychiatry and Neurology. The program includes rotation through the Veterans Administration Hospital, Coatesville, Pa., Veterans Administration Regional Office, Philadelphia, and the Philadelphia General Hospital. Applications should be sent to the Manager, Veterans Administration Hospital, Coatesville, Pa.

"THE BEST IN MEDICINE"

The Veterans Administration opened an exhibit for two weeks beginning May 2 in the Union Station Concourse, Washington, D. C., demonstrating that the Veterans Administration medical program offers veterans "The Best in Medicine."

PUBLIC HEALTH SERVICE

DR. APPLEWHITE TO RETIRE

Dr. Calvin C. Applewhite, who entered the United States Public Health Service in 1915, will retire from the service October 1. He is known in many states especially for helping to build and strengthen local health services. A graduate of Vanderbilt University Medical School, he has for the last eight years been a Regional and District Medical Director for the Public Health Service.

CANCER RESEARCH GRANTS

The Public Health Service announced April 28 additional grants amounting to \$293,452 to support laboratory and clinical research and \$79,853 for research facilities. These grants are in addition to research grants of \$671,200 announced on March 25. The grants for research facilities were \$30,385 to Meharry Medical College, Nashville, Tenn., and \$49,468 to the Institute for Cancer Research in Philadelphia. Among other grants announced is \$30,000 for work at Children's Hospital, Boston, under the direction of Dr. Sidney Farber to attempt to discover more effective chemotherapeutic treatment of leukemia; another grant was \$12,560 to the State University of Florida for work

under the direction of Dr. Francis E. Ray, who will study the experimental production of gastric cancer in animals by chemical means. These grants were recommended by the National Advisory Council at its meeting in March.

NEW MEMBERS OF MENTAL HEALTH COUNCIL

The Surgeon General announces the appointment, effective July 1, of two new members of the National Advisory Mental Health Council. They are Dr. Franz Alexander, director, Chicago Institute for Psychoanalysis, and Dr. S. Bernard Wortis, chairman, Department of Psychiatry, New York University Medical College, replacing Dr. William C. Menninger and Dr. John Romano, whose three year terms on the Council expire. Dr. Alexander received his medical training in Budapest and was director of the Berlin Institute for Psychoanalysis before coming to the United States in 1930. Dr. Wortis, a graduate of Cornell University Medical School, taught at his alma mater and at Johns Hopkins University before going to New York University Medical College in 1942.

MISCELLANEOUS

ACCIDENT RATE IN COAL MINES

The number of American coal miners killed and injured in the nation's coal mines in 1948 in relation to the total man-hours of exposure was lower than in any year except 1944 and 1945, Bureau of Mines Director James Boyd announces. In 1948 the combined fatal and nonfatal injury rate for each million man-hours of exposure to hazards during work was 63.46, the Director said. This was slightly lower than the corresponding rate of 63.62 for 1947 and the rate of 65.35 for 1946. During 1944, when production was at a high level, the combined fatal and nonfatal injury rate per million man-hours was 60.26—lowest on record. A total of 64,989 nonfatal and fatal injuries occurred in 1944 during 1,078,474,377 man-hours of work. In 1948, miners worked 867,500,000 man-hours with a total of 55,055 injuries, 1,010 fatal and 54,045 nonfatal.

On a tonnage basis, the fatal and nonfatal injury rate for 1948 was the best annual record in the statistical history of the nation's coal mining industry. This rate, according to recently revised data, was 84.56 per million tons of coal produced. Part of the improvement shown by the figures calculated

on a tonnage basis is due to higher productivity resulting from increased mechanization and strip mining.

The number of deaths occurring in Pennsylvania anthracite mines in 1948 was estimated at 140, according to recently revised figures, and the fatality rate per million man-hours at 0.92—the best on record. In bituminous coal mines, 870 men lost their lives, and the fatality rate per million man-hours was 1.22. The combined 1948 death rate for both anthracite and bituminous coal mines was placed at 1.16 per million man-hours.

Accident figures for 1948 recently revised by the Bureau also placed the number of nonfatal injuries in anthracite mines at 12,330, and in bituminous coal mines at 41,715. A total of 55,055 men were killed and injured, a 7.3 per cent drop from the number of deaths and injuries in 1947.

In 1948, six major disasters—single accidents in which 5 or more men were killed—resulted in 49 deaths in bituminous coal mines. No major disasters occurred in anthracite mines.

Injury and employment statistics are based on monthly reports received by the Bureau of Mines from bituminous coal and anthracite mines producing about 75 per cent of the coal mined in the United States. All figures are subject to revision.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Report of Eye Bank.—The Stanford University Eye Bank supplied corneas for twenty-four eye graft operations during its second year of operation. Hospitals in San Francisco were the major source of corneas, but eyes were also supplied from Oakland, San Jose, Auburn, Burlingame, Redwood City, Stockton, Tulare and San Diego. Many of the operations performed at Stanford Hospital were on patients from out of town. All Pacific Coast eye surgeons qualified to perform the eye graft operation are eligible to use the services of the Eye Bank, which operates without cost to either patient or surgeon except for a small service fee. Persons who wish to will their eyes to the Eye Bank for use in corneal transplant operations after their deaths may do so through forms available on application to the Eye Bank, Stanford University Hospitals, Clay and Webster Streets, San Francisco.

COLORADO

Harvard Alumni Lecture.—Dr. Marius N. Smith-Petersen, Newton, Mass., gave the second Harvard Lecture at the University of Colorado Medical Center, Denver, May 19. This lectureship is sponsored by the alumni of the Harvard Medical School in the Rocky Mountain region.

Course in Regional Anesthesiology.—An intensive one week postgraduate course in regional anesthesiology will be held at the University of Colorado Medical Center, Denver, June 27 to July 1. The subject will be presented by cadaver dissections, lectures, clinical demonstrations and supervised practice in the various technics covered in the course. The guest lecturer will be Dr. Emery A. Rovenstine, New York University-Bellevue Medical Center. Admission is open to all physicians who are members of their constituent medical societies or the American Medical Association. The registration fee is \$5 and tuition will be \$45. Inquiries should be made to the Director of Graduate and Postgraduate Medical Education, University of Colorado Medical Center, Denver.

CONNECTICUT

Cancer Award to Dr. Smith.—The American Cancer Society on May 4 gave the 1949 Connecticut Cancer Award for distinguished service in cancer control to Dr. George M. Smith of Pine Orchard. The award follows fifty years of service. He has been a member of the Board of Scientific Advisers of the Jane Coffin Childs Fund, medical director of the Anna Fuller Fund and executive director of the National Advisory Cancer Council. In recent years he has helped to guide the cancer work initiated by the National Research Council. Dr. Smith received his medical degree from Columbia University College of Physicians and Surgeons, New York, in 1905. Last year he was named emeritus professor by Yale, which had granted him the LL.D. degree in 1947 largely in recognition of his contributions to the cancer problem.

FLORIDA

Graduate Course in Cardiovascular Diseases.—The Department of Medicine of the Graduate School of the University of Florida announces a special course on cardiovascular diseases, which will be presented June 14-17 at the George Washington Hotel in Jacksonville. The recognition and management of heart conditions of particular interest to physicians in general practice will be featured. Dr. R. Bruce Logue of Emory University School of Medicine, Atlanta, will present the lectures.

ILLINOIS

Camp for Diabetic Children.—A summer camp for diabetic children of the Chicago area is being opened this summer from August 18 to September 1 at Bartlett. The counselors and facilities of Sunset Camp, which is run in conjunction with the James Herrick House for children with crippled hearts, will give diabetic children summer camp experience. The Chicago Diabetes Association will furnish nurses, dieticians and resident physicians trained in the care of diabetic children. Girls from 7 to 16 and boys from 7 to 9 inclusive will be

accepted. Charges are reasonable and may be scaled down if necessary. Application blanks are available to physicians from Mrs. Robert Pennock, chairman, Summer Camp Committee, Chicago Diabetes Association, 1931 Lincoln Park West, Chicago; telephone Yards 7-5600, Ext. 234.

CHICAGO

Dedicate Cancer Exhibit.—The new cancer exhibit at the Museum of Science and Industry was dedicated April 28. Charles F. Kettering, Dayton, Ohio, was the principal speaker. The exhibit, covering 3,200 square feet and financed by the Illinois Division of the American Cancer Society, explains the problems cancer presents and is expected to help speed cancer control. The exhibit was designed and produced under supervision of Professor Thomas S. Jones and Miss Ruth Coleman of the medical illustration department of the University of Illinois. It was opened to the public May 6.

Appoint Superintendent of Tuberculosis Sanitarium.—Dr. Otto L. Bettag, Pontiac, has been appointed medical superintendent and tuberculosis control officer of the City of Chicago Municipal Tuberculosis Sanitarium. The appointment combines two offices formerly held by Dr. George C. Turner, who was medical superintendent, and Dr. Arthur W. Newitt, who resigned several months ago as tuberculosis control officer. Dr. Bettag, medical director and tuberculosis control officer of Livingston County, has been in charge of the tuberculosis section of the Illinois Department of Public Safety for ten years. He has also been thoracic surgeon at the Veterans Administration Hospital, Hines.

Dr. Richard H. Young Named Dean at Northwestern.—Dr. Richard H. Young has been appointed dean of Northwestern University Medical School to succeed Dr. J. Roscoe Miller, who becomes president of the University in July. Dr. Young, now dean of the College of Medicine of the University of Utah, Salt Lake City, is a native Chicagoan, who received his doctor of medicine degree from Northwestern in 1930. After serving an internship and residency at St. Luke's Hospital, Chicago, he did graduate study, principally in hematology, at the University of Oregon Medical School, Portland, and the University College Medical School of the University of London, England. Dr. Young was a member of Northwestern's department of medicine from 1931 to 1945, serving as head of the experimental medicine division the last seven years of that period. In 1945 he became director of the student health service of the university. He was awarded the bronze star for meritorious achievement as a member of the 12th General Hospital staff in the recent war, in which he served as a lieutenant colonel and chief of medicine.

Lay Cornerstone for Cancer Research Hospital.—The cornerstone for the seven story Nathan Goldblatt Memorial Hospital at the University of Chicago was laid May 17. The \$2,500,000 cancer research hospital was established in 1946 with a gift of \$1,000,000 to the university by the Goldblatt Brothers Foundation in memory of Nathan Goldblatt, who died of cancer in 1944. Dr. Leonard Scheele, Surgeon General, U. S. Public Health Service, spoke at the luncheon for the foundation trustees, the women's board and the Nathan Goldblatt Society for Cancer Research, and delivered the principal address at the cornerstone ceremony. Other speakers included President Ernest C. Colwell, Dr. Lowell T. Coggeshall, dean of the division of biological sciences, Maurice Goldblatt, Gov. Adlai Stevenson and Mayor Martin H. Kennelly. This, it is said, will be the first university hospital in the country with the entire staff engaged full time in cancer research and treatment. A second cancer hospital, the Argonne Cancer Research Hospital to be built by the United States Atomic Energy Commission adjacent to the Goldblatt hospital, will also be devoted to full time research treatment of cancer patients with radioactive isotopes.

The Goldblatt Brothers Foundation is a charitable trust established in 1936 by the Goldblatt family to administer their contributions for activities in the fields of social service and medical research.

IOWA

A Course in Clinical Audiometry.—An intensive two week course in clinical audiometry will be offered at the State University of Iowa, Iowa City, June 14-28. The course will include, among other things, lectures on audiometry, lip reading, speech training for the hard of hearing, psychologic problems of the acoustically handicapped and clinical otolaryngology; laboratory work; hearing aid fittings, and demonstrations by John C. Steinberg, Ph.D., of the Bell Telephone Laboratories and Mrs. Bernice Rutherford of the Rehabilitation Center, St. Paul, Minn. For information address: Professor Wendell Johnson, Director, Speech Clinic, State University of Iowa, Iowa City.

MASSACHUSETTS

Dr. Clark to Head Massachusetts General Hospital.—Dr. Dean A. Clark, associate professor of public health practice at Columbia University, has been appointed head of Massachusetts General Hospital, Boston, to succeed Dr. Nathaniel W. Faxon, who has reached the retirement age. Dr. Clark, a graduate of Johns Hopkins University School of Medicine, Baltimore, 1932, was a National Research Council fellow in neurophysiology at Cornell University Medical College; house physician at Phipps Psychiatric Clinic, at Johns Hopkins University in Baltimore, and an intern at Trudeau Sanatorium, Trudeau, N. Y. He was the first chief medical officer of the Federal Office of Vocational Rehabilitation and was on loan to the American Red Cross in 1944-1945 with the rank of surgeon in the regular corps in the U. S. Public Health Service. Since 1945 he has been on leave of absence from the service as medical director of the Health Insurance Plan of Greater New York. He will assume active direction of the hospital as soon as he is relieved of his present responsibilities in New York.

MISSISSIPPI

State Medical Meeting.—The Mississippi State Medical Association held its annual meeting in Biloxi May 10-12, under the presidency of R. B. Caldwell, Baldwin. Out of state speakers included:

Frank T. Mitchell, Memphis, Experience of a Pediatric Consultant in Public Health.

Theodore A. Watters, New Orleans, Common Psychiatric Problems and Psychosomatic Disorders in General Practice.

W. Banks Anderson, Durham, N. C., Congenital and Traumatic Vascular Lesions of the Eye and Adnexia—Kodachrome Clinic.

Lyle M. Sellers, Dallas, Texas, The Frontal Sinus—A Problem in Diagnosis and Treatment.

Jack S. Guyton, Baltimore, Surgery of Horizontal Strabismus.

Arthur J. Walker, New Orleans, Chills and Fever Versus Malaria.

Guy H. Williams and Eric Bell, Cleveland, Present Day Status of Multiple Sclerosis.

Maxwell E. Lapham, New Orleans, Suggested Program for Better Distribution of Medical Service to the Public.

Theo. H. Hanser, St. Louis, Hidden Genito-Urinary Conditions Parading as Abdominal Conditions.

The Ewing Fox Howard oration honoring Dan J. Williams was delivered by Henry Boswell of Sanatorium. The Woman's Auxiliary to the association met May 9-11.

MISSOURI

Personal.—Dr. Robert E. Schlueter, honorary librarian of the St. Louis Medical Society, was given the annual award by the society at a recent dinner meeting. The speakers on the occasion were Dr. Robert E. Kane of St. Louis and Chauncey D. Leake, Ph.D., Galveston, Texas.

Dedicate Headquarters to the Late Dr. O'Reilly.—The recently opened headquarters and clinic of the St. Louis Society for Crippled Children has been dedicated to the late Dr. James A. O'Reilly, who founded the St. Louis society and was for twenty years its president. The one story building is designed to suit specific functions. Front and rear entrances are on ground level; doors are wide enough to permit easy passage of wheel chair patients, and a hallway 35 feet long serves as an exercise corridor. There is also a large playground for the children.

NEW YORK

Graduate Education.—The Medical Society of the State of New York with the cooperation of the New York State Department of Health has arranged the following graduate lectures: Ontario County Medical Society, meeting at the Country Club, Geneva, June 14 at 8 p. m., will hear Dr. G. Gowing Broad, Syracuse, speak on "Diagnosis in Disease of the Anorectum." The Chenango County Medical Society will hear Dr. Charles L. Steinberg, Rochester, speak on "Chronic Arthritis: Its Diagnosis and Management" at its meeting in the Oxford Inn, Oxford, June 14 at 12 noon.

State Sets Up Graduate Scholarships.—For the first time in its history New York has established state scholarships for professional education in medicine and dentistry. The new law fixes the maximum as one hundred and leaves the monetary value and duration to the Board of Regents and the state budget director. The establishment of these graduate scholarships is an outgrowth of studies made by the Temporary Commission on the Need for a State University, which found that economic barriers constituted a substantial handicap for many persons desiring to enter these professions. The law also authorizes the regents with the approval of the budget director to increase the number of undergraduate awards. Formerly these were set at five for each of the one hundred fifty assembly districts of the state. Undergraduate scholarships have carried an annual stipend of \$350 for a four year period.

New York City

Residencies Available.—The Psychiatric Division of the Kings County Hospital, Brooklyn, is expanding its residency training program and has positions available particularly for residents requiring only one more year and seeking third year training. The positions pay \$1,560 with maintenance. Inquiries should be addressed to Dr. Sam Parker, Director of Psychiatry, 606 Winthrop Street, Brooklyn 3.

Personal.—Edward H. L. Corwin, Ph.D., executive secretary of the Committee on Public Health Relations of the New York Academy of Medicine since its founding in 1911, has been appointed associate professor of public health practice in the Columbia University School of Public Health, a part time appointment; Dr. Corwin continues with the academy. —Dr. Benjamin Jablons has been appointed visiting physician (peripheral vascular diseases) at Goldwater Memorial Hospital.

Dr. Bassler Honored.—On the occasion of his fiftieth anniversary in the practice of medicine Dr. Anthony Bassler was guest of honor at a testimonial dinner at the Hotel Commodore, May 1. The speakers included Dr. William Morrison, president of the National Gastroenterological Association; Dr. Martin E. Rehfuess, professor of medicine at Jefferson Medical College of Philadelphia; Msgr. John Curry, head of the Catholic hospitals of New York City, and Rev. Walsh, professor of psychology at Fordham University; Dr. Foster Kennedy, professor of neurology at Cornell University Medical College; Dr. Elihu Katz of the New York Polyclinic; Hon. Ferdinand Pecora and Hon. Peter Schmuck, Judges of the Supreme Court. Dr. Bassler was presented with a book of letters and a gold medal. He is the author of textbooks on gastroenterology.

NORTH CAROLINA

Faculty Appointments.—George O. Doak, Ph.D., chemist of the U. S. Public Health Service, has been appointed associate professor of experimental medicine at the University of North Carolina School of Public Health, Chapel Hill, effective July 1. Dr. Doak has his M.A. and Ph.D. degrees from the University of Wisconsin, Madison. Prior to becoming associated with the Public Health Service he was instructor in medicine and a research associate in bacteriology at Johns Hopkins School of Hygiene and Public Health, Baltimore.

Dr. Frederick A. Thompson Jr. will join the staff of the school of public health July 1 as assistant professor of experimental medicine. He has been assigned by the U. S. Public Health Service as chief of the biology section of the laboratory of experimental medicine. He received his M.D. degree from Duke University School of Medicine, Durham, and at the time of his appointment was serving his residency at Duke Hospital.

OHIO

Fellowships in Industrial Medicine.—The University of Cincinnati is the recipient of a new fellowship in industrial medicine at the Institute of Industrial Health of the University's Graduate School of Arts and Sciences. It was established by the Texaco Company, New York. Two similar fellowships have been granted by the Ethyl Corporation and by the university itself.

Rural Medical Scholarships.—The Ohio State Medical Association has approved a rural medical scholarship plan "to stimulate interest on the part of rural young men and women in the study of medicine, with the belief that because of their interest in rural life, they will later establish medical practice in rural communities." The scholarships will be administered by the Committee on Rural Health, with the aid of an advisory committee composed of representatives from the various rural and educational organizations. Each grant will be \$500 per school year, awarded for a four year period, subject to acceptable work on the part of the student. No obligations other than that will be attached to the scholarship. It is restricted to Ohio residents but may be used at any approved medical school in the country.

RHODE ISLAND

Tom Spies Given Chapin Award.—Dr. Tom D. Spies, professor of nutrition and metabolism and chairman of the department of Northwestern University Medical School, Chicago, received the annual Charles V. Chapin Memorial Award, presented May 11 at the annual dinner meeting of the Rhode Island Medical Society in Providence. The award was established in 1942 by the medical society in honor of the late Dr. Chapin, a native of Providence and one of the foremost public health workers. Dennis J. Roberts, mayor of Providence, presented the award, with a medal provided by a standing

committee of the City Council. Dr. Spies, who is also director of the nutrition clinic at Jefferson-Hillman Hospital, Birmingham, Ala., delivered the Chapin Lecture on "Recent Advances in Nutrition."

TEXAS

Personal.—Dr. Carl A. Moyer, professor of experimental surgery at Southwestern Medical College, Dallas, was the 1949 recipient of the Dallas Southern Clinical Society's Marchman Award for research into the fluid balance of the human body.

Gift for X-Ray Equipment.—The Sealy and Smith Foundation of Galveston has given \$22,000 to the John Sealy Hospital of the University of Texas Medical Branch, Galveston, for x-ray equipment in the Special Surgical Unit under the direction of Dr. Truman G. Blocker Jr., Galveston. The Special Surgical Unit, accommodating fifty-six beds, is devoted to plastic and maxillofacial surgery and neurosurgery.

Nobel Prize Winner Lectures.—The annual lectureship sponsored by Alpha Omega Alpha, honorary medical fraternity, at the University of Texas Medical Branch, Galveston, was given this year by Arne Tiselius, Ph.D., professor of biochemistry at the University of Uppsala, Sweden, and Nobel laureate for 1948. Professor Tiselius discussed the application of chromatographic methods to clinical problems. At the annual initiation and banquet of Alpha Omega Alpha, Professor Tiselius described the development of dextrane as a plasma substitute.

VERMONT

Course in Cardiovascular Disease.—The Cardiovascular Unit, recently established on a cooperative basis by the College of Medicine of the University of Vermont, Burlington, and the Bishop DeGoesbriand Hospital in Burlington, will conduct a refresher course on cardiovascular disease June 13-18. Guest speakers will be Dr. Paul D. White, Harvard Medical School, Boston, and a consultant of the National Heart Institute, and Dr. Mercier Fauteux, McGill University, Montreal, Canada. In addition 12 members of the University of Vermont medical faculty will take part in the program.

Study of Tendon Transplantation.—The National Foundation for Infantile Paralysis announces a one year grant to the division of orthopedic surgery of the University of Vermont College of Medicine, Burlington, for a study of the results of tendon transplantation, particularly in the lower extremities. The work will be carried out by Dr. Raymond Kuhlman, fellow in orthopedic surgery, under the direction of Dr. John F. Bell, associate professor in that division. The follow-up service of the Crippled Children's Division of the Department of Health will cooperate in the study.

WEST VIRGINIA

Personal.—Dr. Delivan A. MacGregor, of Wheeling, has been appointed by Dr. Thomas G. Reed, Charleston, president of the West Virginia State Medical Association, as a member of the advisory committee to the United Mine Workers Welfare and Retirement Fund. He will represent the Northern Panhandle. Dr. Ray M. Bobbitt, of Huntington, is chairman of the committee and the other members are Drs. Fred Richmond, of Beckley, and John P. Helmick, of Fairmont.

Licenses Revoked.—The licenses of the following doctors to practice medicine in West Virginia have been revoked: Wilkin R. Stevens, of Welch, license no. 6473, dated July 10, 1941, and Lawrence T. Browning, license no. 5394, dated Dec. 14, 1927. The orders entered by the public health council assigned as the reason for the revocation in each of these cases the doctor's conviction of a felony charge.

State Health Conference.—The annual State Health Conference, combining sessions of the State Health Officers' Conference and the West Virginia Public Health Association, will be held June 2-3 at the Daniel Boone Hotel, Charleston. At the general session Dr. Newman H. Dyer, state health commissioner, Charleston, will speak on "Public Health Forecast"; Dr. John D. Porterfield, director of health, Columbus, Ohio, on "Local Health Problems," and Dr. Russell C. Bond, Wheeling, on "The West Virginia Pediatric Study." Guest speaker at the banquet Thursday evening will be Dr. James G. Townsend of the U. S. Public Health Service, Washington, D. C., whose subject will be "Atmospheric Pollution." A panel discussion on "Integrating Services to Serve the Public" will be held Friday after section meetings. At 7:30 p. m. Friday Roy E. Dickerson, executive secretary of the Cincinnati Social Hygiene Society, will discuss "What Is Family Life Education?"

HAWAII

Territorial Medical Election.—At the annual meeting of the Hawaii Territorial Medical Association May 7 in Honolulu. Dr. Howard E. Crawford, Hilo, became president and Dr. Rogers Lee Hill, Honolulu, was chosen president elect. Drs. Irvin L. Tilden and Edwin K. Chung-Hoon, both of Honolulu, were elected secretary and treasurer respectively for three year terms.

Enlarge Blood Bank.—The Blood Bank of Hawaii, Honolulu, is to be enlarged by a 16 by 80 foot extension to the building to meet increasing demand for blood and blood products. The growing volume of service reflects expanded and improved procedures for processing and using blood rather than a rise in the number of donors, according to Dr. Forrest J. Pinkerton, director. The blood bank is now giving transfusions in its own offices to persons referred there by physicians, a practice that results in a saving to patients of time and money. The bank services twenty-eight hospitals on four islands, and the average civilian patient load has gone up from about 300 per month in wartime to nearly 1,000. During the war blood was simply turned over to the military, who prepared their own equipment for administering it. For most civilian hospitals, however, the blood bank prepares the administration sets. Rh typing, done only sporadically during the war, is now a routine process at the blood bank.

Another process developed at the bank since the war is the titration of all type O bloods. The blood bank is a nonprofit organization operating for the benefit of the community. It charges patients \$7.50 for service and requests replacement of blood by a donor, setting \$42.50 as the charge for the blood, to discourage patients from buying it outright. In 1948 the bank accepted blood of 10,186 persons. Over 90 per cent of the demand is for whole blood. When unused blood becomes outdated, it is processed into plasma. Dr. Pinkerton has recently completed arrangements with Irwin Memorial Blood Bank of San Francisco and the Blood Bank Commission of the California State Medical Association for mutual assistance in the event of war or a community disaster of catastrophic proportions. A similar agreement with the bank in Seattle is now under consideration.

GENERAL

University of Pennsylvania Class Reunion.—The 1939 class of the University of Pennsylvania School of Medicine, Philadelphia, will hold a reunion and supper in the Solarium of the Claridge Hotel, Atlantic City, N. J., June 5, from 5 to 7 p. m.

Hahnemann Medical Alumni Reunion.—An alumni reunion of the Hahnemann Medical College will be held June 8 at 6 p. m. in the Chalfonte Music Room, Chalfonte-Haddon Hall, Atlantic City, N. J. Tickets may be purchased in advance from the college alumni office.

Tuberculosis Physicians Meeting.—The American Academy of Tuberculosis Physicians will hold its annual meeting June 4 at the Hotel Dennis, Atlantic City, N. J., under the presidency of Dr. Robert A. Peers, Colfax, Calif. Presentation of awards will take place at the luncheon at 12:30 p. m.

\$250,000 for Research on Heart Disease.—Research grants totaling \$250,000 have been allocated by the American Heart Association to 26 investigators and 6 medical schools and hospitals for studies in heart and circulatory diseases. Award selections were made from among 121 requests totaling \$1,400,000. Dr. Tinsley R. Harrison, Dallas, president of the American Heart Association, stated that "All the requests were of high caliber and deserving of fulfillment."

Librarian Honored.—Mrs. Eileen R. Cunningham, librarian of the Vanderbilt University School of Medicine, Nashville, Tenn., has been chosen the first recipient of the Medical Library Association's Marcia C. Noyes Award in recognition of her achievements in medical librarianship. Mrs. Cunningham is the author of "Classification for Medical Literature," now in its third edition. She has held offices in numerous library associations and has served on many of their committees.

Electroencephalographic Society Meeting.—The American Electroencephalographic Society will hold its annual meeting at the Chalfonte-Haddon Hall, Atlantic City, N. J., June 11-13, under the presidency of Dr. Frederick A. Gibbs, Chicago. The program includes a symposium on corticothalamic pathways to be held Sunday morning under the chairmanship of Dr. A. Earl Walker, Baltimore. The symposium is being held in collaboration with the American Branch of the International League Against Epilepsy.

Meeting on Medical Missions.—All physicians and medical students are cordially invited to attend a public meeting on overseas mission medical work at 8 p. m. June 5, in the Central Methodist Church, 1213 Pacific Avenue, Atlantic City, N. J. Several outstanding medical missionaries will give accounts of their work abroad. A motion picture on medical mission work in the Congo will be shown. The meeting is sponsored by the Christian Medical Council for Overseas Work.

Awards for Rehabilitation Work.—The National Council for Rehabilitation, at a meeting at the Astor Hotel, New York, April 21, conferred 1949 awards on Lionel Barrymore, Thomas E. Millso, president of the Weirton Steel Company and Dr. Royd R. Sayers, medical director of the United Mine Workers of America, for their activities in behalf of the disabled. Dr. Henry H. Kessler, Newark, N. J., was reelected head of the council.

Meeting of Physical Therapy Association.—The American Physical Therapy Association will hold its annual conference at the Copley Plaza Hotel, Boston, June 19-24. Among the subjects to be presented are "Rehabilitation of the Hemiplegic Patient," "Neurological Aspects of Cerebral Palsy," "Polio-myelitis," "Multiple Sclerosis," "Some Research Problems in Physical Therapy," "Some Psychiatric Problems Related to Arthritis" and "Fractures." On Friday afternoon various physical therapy clinics in the Boston area will hold "open house."

Research Fellowships in Medicine.—The American College of Physicians announces that a limited number of fellowships in medicine will be available from July 1, 1950 to June 30, 1951. These fellowships are designed to provide an opportunity for research training either in the basic medical sciences or in the application of these sciences to clinical investigation. They are for the benefit of physicians who are in the early stages of their preparation for a teaching and investigative career in internal medicine. The stipend will be from \$2,200 to \$3,000. Application forms will be supplied on request to the American College of Physicians, 4200 Pine Street, Philadelphia 4, and must be submitted in duplicate not later than Oct. 1, 1949.

Award Abel Prize in Pharmacology.—At the Detroit meeting of the American Society for Pharmacology and Experimental Therapeutics, Mark Nickerson, Ph.D., assistant professor of pharmacology, University of Utah, College of Medicine, Salt Lake City, was awarded the 1949 John J. Abel Prize in Pharmacology for his research on "Pharmacology of the B-Haloalkylamines: a New Class of Adrenergic Blocking Agents." This prize of \$1,000 and a bronze medal has been donated to the society by the Eli Lilly Co., Indianapolis. The 1950 prize will be awarded at the Atlantic City meeting of the society to be held the week of April 9, 1950. Information concerning this award can be obtained from the secretary of the society, Dr. Harvey B. Haag, Medical College of Virginia, Richmond 19, Va.

World Medical Association Publishes Bulletin.—The first issue of the *World Medical Association Bulletin*, a quarterly, appeared in April under the editorship of Dr. Morris Fishbein, Chicago, and nine collaborating editors representing several other nations. The same articles appear in English, French and Spanish in corresponding columns of its 32 pages. The bulletin is not to be a medical journal; "Its purpose is wholly in the field of medicine as related to social advancement, to government, to war, and to the standards of medical care." The World Medical Association was established in Geneva in 1947 to raise the standards of medical education throughout the world and, correlated with this, the delivery of the highest quality of medical service. The \$10 World Medical Association annual fellowship dues, which should be sent to the association's address, 2 East 103rd Street, New York 29, includes subscription to the bulletin.

Recommendations on Maternal and Child Health.—A series of proposals were formulated by the World Health Organization's Expert Committee on Maternal and Child Health, which met in Geneva in January. These are to serve as the basis for discussion and action at the second World Health Assembly in Rome in June. Among the recommendations were the following: establishment of a special Health Education Service within the World Health Organization; stimulation of research and provision of information to governments in the form of monographs and bibliographies; sending of expert advisers and demonstration teams to countries requesting them; expansion of the existing fellowship program and stimulation of training of nurses, midwives; close cooperation with UNICEF in mass immunization campaigns and development of child guidance clinics, and with UNICEF and FAO in stimulating production and distribution of safe milk.

Vascular Surgeons' Meeting.—The Society for Vascular Surgery is holding its annual session June 5 at the Hotel Dennis in Atlantic City, N. J. All physicians are welcome to attend. The program is as follows:

George D. Lilly and Robert M. Lee, Miami, Fla., Complications of Anti-Coagulant Therapy.

Julian Johnson, Philadelphia, Experimental and Clinical Use of Vein Grafts to Replace Large Arteries.

Michael Radakovich and W. J. Merle Scott, Rochester, N. Y., Venous and Lymphatic Stasis in the Lower Extremities.

Richard Warren, Boston, Venous Pressures in the Lower Extremities as a Pre-Operative Study to Determine a Method of Treatment for Varicose Veins.

Thomas L. Stokes and John H. Gibbon Jr., Philadelphia, Observations on the Temporary Artificial Maintenance of the Circulation.

Emile Holman, San Francisco, President's Address: Problems in the Dynamics of Blood Flow.

Davitt A. Felder, Fiorindo A. Simeone and Robert R. Linton, Boston, Evaluation of Sympathetic Neurectomy in Raynaud's Disease.

Helen B. Taussig, Baltimore, Diagnosis and Differential Diagnosis of Cyanotic Malformations Amenable to Surgery.

Kenneth N. Campbell, Detroit; Bradley M. Harris, Ypsilanti, Mich., and Frederick A. Collier, Ann Arbor, Mich., Follow-Up Study of Patients with Thrombo-Angiitis Obliterans.

Lewis H. Bosher Jr. and Isaac A. Bigger, Richmond, Va., Study of Collateral Circulation Following Excision of Arteriovenous Fistulas.

Harris B. Shumacker Jr., Indianapolis, Study of Factors Influencing Effect of Arterio-Venous Fistulas on Size of the Heart.

Irving Leinwand, J. William Hinton and Jere W. Lord Jr., New York, Hypertensive Vascular Disease with Quadrilateral Raynaud's Syndrome Treated by Total Sympathectomy.

Dinner will be at 7 p. m.

Special Society Elections.—The American Association of Pathologists and Bacteriologists at its recent meeting in Boston elected Drs. Shields Warren, Alan R. Moritz and Sidney Farber, all of Boston, president, secretary and treasurer, respectively.—At the annual meeting of the Association of Schools of Public Health in Ann Arbor, Mich., last year's officers were reelected. They are: Brigadier General James S. Simmons, Boston, president, and Dr. Gaylord Anderson, Minneapolis, secretary-treasurer.—The Southeastern Section of the American Urological Association at its recent annual meeting installed Dr. James J. Ravenel, Charleston, S. C., as president and chose Drs. Edgar Burns, New Orleans, president elect and Russell B. Carson, Fort Lauderdale, Fla., secretary-treasurer.—At the fourth annual meeting of the Council of the New England State Medical Societies held recently in Boston, Dr. Norman A. Welch, physician in chief at Carney Hospital, Boston, was elected president and Dr. Roland E. McSweeney, Brattleboro, Vt., president of the Vermont State Medical Society, vice president. John E. Farrell, Sc.D., executive secretary of the Rhode Island Medical Society, was reelected secretary-treasurer.—The American Academy of Orthopaedic Surgeons at its meeting in Chicago in January installed Dr. Mather Cleveland, New York, as president, and chose Dr. Guy Caldwell of Tulane University of Louisiana School of Medicine, New Orleans, as president elect. Dr. H. Relton McCarroll is treasurer and Dr. Harold B. Boyd, Memphis, Tenn., secretary.—The American Society of Pharmacology and Experimental Therapeutics at its Detroit meeting April 18-22 elected Drs. Carl F. Schmidt, Narberth, Pa., as president, Harvey B. Haag, Richmond, secretary, and Ko Kuei Chen, Indianapolis, treasurer.—The American Society for Clinical Investigation at its meeting in Atlantic City May 2 chose T. Hale Ham, Brookline, Mass., as president.

Marriages

CHARLES W. HOFFMAN JR., Baltimore, to Miss Tove Poulson of Perth Amboy, N. J., in Fort Dix, N. J., April 30.

WALDRON RAYMON GARDINER JR., to Miss Jacqueline Sabina Heims, both of San Francisco, April 30.

HAROLD JACK TAUSEND, Houston, Texas, to Miss Mary Louise Nesbit of Madison, Wis., April 23.

MALACHI WILSON SLOAN II, Detroit, to Miss Jane Mayne Taylor of Allentown, Pa., April 23.

SAMUEL EARL UPCHURCH to Miss Alia Ann Samford, both of Birmingham, Ala., April 20.

HOMER CURTISS MERRICK JR., to Miss Margaret Anne Paul, both of Norfolk, Va., April 10.

HUGH MCINTYRE CALDWELL to Miss Vivian Laura Moll, both of Columbus, Wis., April 28.

ROBERT R. GILLESPIE JR. to Miss Sena Rae Matthews, both of Birmingham, Ala., April 26.

ROBERT BRAGG HAGOOD, Lowndesboro, Ala., to Miss Georgia Bell of Fayetteville, April 9.

Deaths

Eugene Hillhouse Pool • Locust Valley, N. Y.; born in New York June 3, 1874; Columbia University College of Physicians and Surgeons, New York, 1899; emeritus professor of clinical surgery at the Cornell University Medical College in New York; joined the faculty of his alma mater as assistant demonstrator of anatomy in 1901; rose through the ranks until, in 1915, he was named professor of clinical surgery, holding that post until 1938; in 1948 retired as a life trustee of Columbia University, a position he had held since 1939, after having served as an alumni representative; a member of the consulting board of cancer research at Columbia; secretary of the Section on Surgery of the American Medical Association from 1916 to 1919 and chairman in 1922 and 1923; past president of the New York Academy of Medicine, American College of Surgeons and the American Surgical Association; member of the International Surgical Association, Southern Surgical Association and the Society of Clinical Surgery; fellow of the American College of Surgeons; member of the founders group of the American Board of Surgery; decorated for distinguished service with the medical corps of the American Expeditionary Forces in France, at which time he served as a lieutenant colonel and directed surgical work in the St. Mihiel and Meuse-Argonne offensives; served as surgeon on the advisory board of the New York City committee of the American Society for the Control of Cancer; as a representative of the New York Academy of Medicine, appointed by Governor Lehman in 1933 as chairman of a committee that studied medical abuses in connection with the administration of the Workmen's Compensation Law; in 1934 was named administrative consultant in surgery for all the city hospitals in New York; formerly on the joint administrative board of the Columbia-Presbyterian Medical Center; served as senior attending surgeon of the New York Hospital and surgeon in chief emeritus of the Hospital for the Ruptured and Crippled; consulting surgeon, Presbyterian, French, Harlem and Woman's hospitals, New York Infirmary for Women and Children, the North Country Community Hospital in Glen Cove, the Elizabeth A. Horton Memorial Hospital in Middletown, N. Y., the Monmouth Memorial Hospital in Long Branch, N. J., the United Hospital in Port Chester, N. Y., the New York Eye and Ear Infirmary and Central Islip (N. Y.) State Hospital; died April 9, aged 74.

Robert Moseley Yergason • Hartford, Conn.; born in Hartford Oct. 3, 1885; Columbia University College of Physicians and Surgeons, New York, 1909; specialist certified by the American Board of Orthopaedic Surgery; member of the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; served during World War I; visiting orthopedic surgeon, St. Francis and Mount Sinai hospitals in Hartford, and Home for Crippled Children, Newington; consulting orthopedic surgeon, Veterans Administration Hospital in Newington, Manchester Memorial Hospital in Manchester, Windham Community Memorial Hospital in Williamstown, Meriden Hospital in Meriden, Day Kimball Hospital in Putnam, William W. Backus Hospital in Norwich, Litchfield County Hospital in Winsted and Neuro-Psychiatric Institute of the Hartford Retreat; awarded the Silver Beaver by the Boy Scouts of America; died in St. Francis Hospital March 24, aged 63, of pneumonia.

Irving Hotchkiss Pardee • New York; born in New York Jan. 26, 1892; Columbia University College of Physicians and Surgeons, New York, 1915; professor of neurology and executive officer of the department of neurology at his alma mater; member of the Association for the Study of Internal Secretions; member and formerly vice president of the Association for Research in Nervous and Mental Disease and the American Neurological Association; past president of the New York Neurological Society; served with the American Expeditionary Forces during World War I; affiliated with the Hospital for Special Surgery, New York Neurological Institute and St. Luke's Hospital in New York, Yonkers (N. Y.) General Hospital, Tuxedo Memorial Hospital, Tuxedo Park, and the North Country Community Hospital in Glen Cove; died in the New York Hospital April 10, aged 57.

Joe R. Clemmons • New York; born in Longview, Texas, Sept. 4, 1896; University of Tennessee College of Medicine, Memphis, 1924; member of the American College of Hospital Administrators, American Public Health Association and the American Hospital Association; for many years director of the Associated Hospital Service; served in France during World War I; cited by President Truman for his work as chairman of the New York State Procurement and Assignment

Service for Physicians, which recruited doctors for the armed forces in World War II; formerly assistant director of Strong Memorial Hospital in Rochester, N. Y., and medical superintendent of the Macon (Ga.) Hospital; for many years medical director and executive vice president of Roosevelt Hospital, where he died April 2, aged 52.

David Hastings Atwater • Rochester, N. Y.; Syracuse University College of Medicine, 1902; for many years county coroner; served during World War I; died in Strong Memorial Hospital February 7, aged 73, of cerebral hemorrhage.

Paul Eve Bain, Pawnee, Ill.; Barnes Medical College, St. Louis, 1899; died March 7, aged 70, of coronary occlusion and prostatitis.

Henry Lester Baker • Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; an Associate Fellow of the American Medical Association; died March 5, aged 79, of coronary heart disease.

George Tilman Banker • Elizabeth, N. J.; Cornell University Medical College, New York, 1911; in 1946 received a certificate of appreciation from the War Department for three or more years on the Induction Examining Board in Newark; member of the board of education; on the staff of Elizabeth General Hospital; died in Plainfield March 6, aged 66, of heart disease.

James Nelson Barger, Albany, Mo.; University Medical College of Kansas City, Mo., 1898; died in St. Francis Hospital, Maryville, March 1, aged 75, of multiple sclerosis.

Andrew Peter Barnai, Chicago; Regia Università degli Studi di Bologna. Facoltà di Medicina e Chirurgia, Italy, 1937; member of the American Medical Association; served during World War II; affiliated with the Chicago State Hospital; died April 17, aged 35.

George Calvin Berkheimer, Windber, Pa.; College of Physicians and Surgeons, Baltimore, 1905; member of the American Medical Association; past president of the Somerset County Medical Society; died in Philipsburg March 4, aged 77, of cerebral hemorrhage.

Bo Carr Howell, La Porte, Ind.; College of Physicians and Surgeons of Chicago, 1895; formerly county coroner; on the staff of Holy Family Hospital and Fairview Hospital, where he died March 2, aged 79, of cerebral hemorrhage.

Pierre Brunelle, Lowell, Mass.; McGill University Faculty of Medicine, Montreal, Canada, 1896; member of the American Medical Association; served as chairman of the city board of health; died February 11, aged 76, of cerebral hemorrhage.

Joseph Aaron Carter, Seattle; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1898; served during World War I; died in the Veterans Administration Hospital March 8, aged 82, of cerebral hemorrhage.

James Burnett Clark, Springfield, Mo.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1909; died in Kansas City, March 1, aged 78, of uremia.

Arthur Hiram Congdon • Schenectady, N. Y.; Albany (N. Y.) Medical College, 1915; on the staff of Ellis Hospital; died in Richmond, Va., March 4, aged 58, of coronary occlusion.

George Lindsay Cook • Tampa, Fla.; University College of Medicine, Richmond, 1913; specialist certified by the American Board of Pediatrics, Inc.; member of the American Academy of Pediatrics; fellow of the American College of Physicians; on the staffs of Tampa Municipal and St. Joseph's hospitals; died March 8, aged 62, of heart disease.

Ninian J. Cooper, Kramer, Pa.; College of Physicians and Surgeons, Baltimore, 1894; died March 7, aged 83, of arteriosclerosis.

Baron Francis Cornett, Bluefield, W. Va.; Atlanta College of Physicians and Surgeons, 1902; died in St. Luke's Hospital, February 18, aged 76, of carcinoma of the rectosigmoid.

Louis Ward Croke • Boston; Tufts College Medical School, Boston, 1911; formerly faculty member of the Massachusetts Institute for Technology; affiliated with the Liberty Mutual Insurance Company; died February 15, aged 63, of cardiac decompensation, amputation of right leg in April 1947, and embolism.

Donald Ray Davis • Dodge City, Kan.; University of Southern California School of Medicine, Los Angeles, 1939; served overseas during World War II; died in Wichita, March 4, aged 36, of uremia and streptococcal septicemia.

Albert Simeon Dolloff * Goshen, Conn.; Dartmouth Medical School, Hanover, N. H., 1891; an Associate Fellow of the American Medical Association; member of the New Hampshire Medical Society; died in Torrington, March 6, aged 86, of cardiorenal vascular disease.

Harry Edward Dorwart * Lexington, Neb.; Creighton University School of Medicine, Omaha, 1927; died recently, aged 45, of coronary disease.

Sim Driver * Dallas, Texas; Baylor University College of Medicine, 1920; clinical associate professor of orthopedic surgery at the Southwestern Medical College; member of the Clinical Orthopaedic Society and the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; served during World War I; on the staffs of the Baylor University, St. Paul's, Methodist, Medical Arts and Parkland hospitals; died in the Gaston Hospital February 27, aged 58, of mesenteric thrombosis.

Maurice Samuel Duchin, Cambridge, Mass.; Chicago Medical School, 1930; died in Peter Bent Brigham Hospital, Boston, February 5, aged 46.

James Henry Gasson, Shenandoah, Iowa; John A. Creighton Medical College, Omaha, 1898; member of the American Medical Association; died in the Iowa Methodist Hospital, Des Moines, March 5, aged 79, of myocardial infarction and coronary sclerosis.

Louis Herbert Gaus, Albany, N. Y.; Albany Medical College, 1907; served during World War I; consulting oculist to the Moses-Ludington Hospital, Ticonderoga; medical adviser for Selective Service during World War II; died in St. Peter's Hospital, March 6, aged 64, of coronary occlusion.

Joseph Enoch Gichner, Baltimore; University of Maryland School of Medicine, Baltimore, 1890; member of the American Medical Association; professor of clinical medicine and physical therapy emeritus at his alma mater; died March 8, aged 85, of gangrene of the left foot and generalized arteriosclerosis.

Joseph Goethe Graver, Cleveland; College of Physicians and Surgeons, Baltimore, 1907; member of the American Medical Association; on the staffs of the University Hospitals; died in Cleveland Clinic Hospital February 9, aged 68, of coronary occlusion.

Frank Joseph Guenther, La Grange, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1909; member of the American Medical Association; past president of the Fayette County Medical Society; county health officer; affiliated with La Grange Hospital; died March 4, aged 63, of heart disease.

Darwin Walton Hall * Kansas City, Mo.; University Medical College of Kansas City, 1896; an Associate Fellow of the American Medical Association; died March 3, aged 75, of coronary thrombosis.

Aldace Walker Hammond * Beaver Dam, Wis.; Rush Medical College, Chicago, 1920; for many years health officer; on the staffs of Lutheran Deaconess and St. Joseph's hospitals; died March 10, aged 56, of coronary thrombosis.

Louis Everett Hanisch * Omaha; University of Nebraska College of Medicine, Omaha, 1916; instructor in surgery at his alma mater; fellow of the American College of Surgeons; served in France during World War I; affiliated with the Lutheran Hospital; died March 13, aged 59, of coronary occlusion.

Clarence Edwin Harco * Newcomerstown, Ohio; Hahnemann Medical College and Hospital of Philadelphia, 1945; served during World War II; died in February, aged 29.

Isaac Carrington Harrison, Danville, Va.; University of Virginia Department of Medicine, Charlottesville, 1895; member of the American Medical Association; past president of the Medical Society of Virginia; served on the state board of medical examiners, as chairman of the school board and as a member of the police commission; on the staffs of Hilltop Sanatorium and Memorial Hospital; died in Westbrook Sanatorium, Richmond, March 12, aged 78, of pneumonia following fracture of a hip as the result of a fall.

John George Henson, Huntley, Ill.; Chicago College of Medicine and Surgery, 1908; served during World War I; on the staffs of Sherman Hospital and St. Joseph Hospital in Elgin; died February 27, aged 65, of coronary embolism.

Harry Campbell Hill * Streator, Ill.; Rush Medical College, Chicago, 1894; an Associate Fellow of the American Medical Association; died March 9, aged 79, of coronary occlusion.

Alwin Joseph Holden, Chicago; Bennett Medical College, Chicago, 1915; served during World War II; died in American Hospital February 25, aged 54, of bronchopneumonia.

Foster Miller Hull, El Monte, Calif.; College of Physicians and Surgeons, Los Angeles, 1912; died February 8, aged 60.

Donald Henry Jessop * Portland, Ore.; University of Oregon Medical School, Portland, 1909; fellow of the American College of Surgeons; on the staff of St. Vincent's Hospital; formerly chief surgeon of the Union Pacific Railroad Company; died March 9, aged 73, of cerebral accident and Parkinson's disease.

Lewis Karnopp * Wautoma, Wis.; College of Physicians and Surgeons of Chicago, 1894; served during World War I; local surgeon for the Chicago and Northwestern Railroad for many years; died March 5, aged 78, in a motor car accident.

Ronald Bradshaw Kieffer * Toledo, Ohio; Ohio State University College of Medicine, Columbus, 1937; formerly practiced in Napoleon, Ohio, where he was county coroner; served on the staff of the William W. Roche Memorial Tuberculosis Hospital; died March 1, aged 39, of tuberculosis.

Second Herbert Large, Cleveland; Trinity Medical College, Toronto, Canada, 1893; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology, of which he had been treasurer and comptroller, American Laryngological Association and American Laryngological, Rhinological and Otolological Society; on the staff of St. Vincent Charity Hospital, where he died in March, aged 76, of coronary insufficiency, Buerger's disease and glaucoma.

Jacques Lewinski, Brooklyn; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1912; died in the Bushwick Hospital March 5, aged 61, of coronary disease.

William Bruce Lunsford, Winchester, Mass.; Vanderbilt University School of Medicine, Nashville, Tenn., 1913; served during World Wars I and II; formerly on the staffs of various Veterans Administration hospitals; died March 6, aged 58, of hypertensive encephalopathy.

Asa Calvier De McClellan, Lockland, Ohio; Meharry Medical College, Nashville, 1909; died February 4, aged 67, of heart disease.

Kenith Smith McIntyre * Hastings, Mich.; University of Michigan Medical School, Ann Arbor, 1925; served during World War II; past president of the Barry County Medical Society; affiliated with Pennock Hospital; died February 20, aged 47.

Lewis Steele McQuade, Quincy, Mass.; Tufts College Medical School, Boston, 1907; member of the American Medical Association; served during World Wars I and II; affiliated with the Veterans Administration Hospital; died in St. Margaret's Hospital, Boston, March 10, aged 66, of subacute virus hepatitis.

Charles Allen McWilliams * Gulfport, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1913; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served during World War I; on the staff of Memorial Hospital, where he died March 9, aged 61, of cerebral hemorrhage.

Edwin Herman Maercklein, Ashley, N. D.; Milwaukee Medical College, 1903; served during World War I; died in Veterans Administration Hospital, Minneapolis, March 7, aged 68, of bronchogenic carcinoma, squamous cell, with metastases to lung and kidney.

Ralph Justin Malott * Scottsbluff, Neb.; Northwestern University Medical School, Chicago, 1920; on the staff of St. Mary's Hospital and the Western Nebraska Methodist Episcopal Hospital, where he died February 16, aged 56, of pulmonary edema.

Elviro Mancusi-Ungaro * Newark, N. J.; University and Bellevue Hospital Medical College, New York, 1917; consulting pediatrician to the Essex County Sanatorium; on the staff of St. James and the American Legion hospitals; died March 9, aged 55, of portal cirrhosis.

Kossuth A. Mayer, Lower Peach Tree, Ala.; Memphis (Tenn.) Hospital Medical College, 1900; member of the American Medical Association; member of the board of censors of the Medical Association of the State of Alabama; died March 3, aged 71, of coronary thrombosis.

Harold Abiud Miller ☉ Lansing, Mich.; University of Michigan Medical School, Ann Arbor, 1916; died in St. Lawrence Hospital March 2, aged 57, of hypertensive heart disease.

William Mitchell, Needham, Mass.; McGill University Faculty of Medicine, Montreal, Canada, 1894; died March 15, aged 76.

Neil C. Monroe, Rogers City, Mich.; Medical College of Indiana, Indianapolis, 1898; died February 26, aged 76, of cerebral thrombosis and cardiac embolism.

Lucius D. Morgan, Gladys, Va.; Medical College of Virginia, Richmond, 1903; member of the American Medical Association; died March 10, aged 78, of carcinoma of the kidney and bladder.

Byron O. Mork Sr., ☉ Worthington, Minn.; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1907; on the staff of Worthington Hospital; died March 2, aged 81, of cerebral arteriosclerosis.

Joseph Patrick Mulhern ☉ Worcester, Mass.; Tufts College Medical School, Boston, 1918; fellow of the American College of Surgeons; served during World War I; examining physician for local board 164 during World War II; visiting surgeon, orthopedic service, St. Vincent Hospital; on the courtesy staff, orthopedics, Hahnemann Hospital; consulting surgeon, orthopedics, Worcester City Hospital, where he was president of the board of trustees, died March 6, aged 57, of aortic stenosis.

Franklin Spilman Newell, Boston; Harvard Medical School, Boston, 1896; professor of clinical obstetrics emeritus at his alma mater; member of the American Medical Association; member and past president of the American Gynecological Society; served as chief of staff and trustee of Boston Lying-in Hospital; died March 3, aged 77, of carcinoma of the stomach.

David Nussbaum, Hilltown, Pa.; Medizinische Fakultät der Universität Wien, Austria, 1906; specialist certified by the American Board of Otolaryngology; formerly on the faculty of the Graduate School of Medicine, University of Pennsylvania in Philadelphia, where he was on the staffs of Northern Liberties and Mount Sinai hospitals; died in Haver-town, recently, aged 63, of coronary thrombosis.

Madison Knox Patton, Selma, Ala.; Medical Department of Tulane University of Louisiana, New Orleans, 1891; died February 16, aged 80, of chronic endocarditis and myocarditis.

Samuel Charles Pierce, Richmond, Calif.; University of Louisville (Ky.) Medical Department, 1900; died in Martinez, February 13, aged 78, of carcinoma of the pancreas, acute cholangitis and cholecystitis.

Bradbury Norton Robinson, St. Louis, Mich.; St. Louis University School of Medicine, 1908; died in St. Petersburg, Fla., March 7, aged 65, of heart failure.

Orville Rockwell ☉ Sunnyside, Wash.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1906; superintendent of the Nebraska Sanitarium in Lincoln from 1907 to 1913; chief surgeon, Boulder-Colorado Sanitarium from 1931 to 1936; died suddenly, March 4, aged 69, of coronary occlusion.

Cuthbert Harry Rogerson ☉ Baltimore; L.R.C.P., London and M.R.C.S., England, 1931; served as director of Seton Institute, formerly known as Mount Hope Retreat; at one time medical superintendent of Cassel Hospital, Swaylands, England; died February 10, aged 39, of glioblastoma.

Carl Webber Rosenbloom, Holyoke, Mass.; Tufts College Medical School, Boston, 1909; member of the American Medical Association; died March 2, aged 64, of bulbar paralysis.

Frank Tipton Rudy, Columbus, Ohio; Medical College of Indiana, Indianapolis, 1892; died in Grant Hospital March 2, aged 83, as the result of a fall.

William Van Buren Saul, Montpelier, Miss.; University of Louisville (Ky.) Medical Department, 1880; member of the American Medical Association; died February 4, aged 91.

Arthur Sayer ☉ New York; Columbia University College of Physicians and Surgeons, New York, 1919; associate professor of dermatology at the New York University College of Medicine; specialist certified by the American Board of Dermatology and Syphilology; served in the U. S. Navy during World War II; affiliated with the U. S. Naval Hospital in St. Albans, N. Y., Mount Sinai Hospital and Morrisania City Hospital; died February 22, aged 55, of coronary thrombosis.

Samuel Benjamin Scholz ☉ Jenkintown, Pa.; Denver and Gross College of Medicine, 1905; fellow of the American College of Physicians; veteran of the Spanish-American War; served as president of the Association of Life Insurance Medical Directors; retired medical director and formerly second vice president of the Penn Mutual Life Insurance Company in Philadelphia; died March 4, aged 70, of coronary occlusion.

John Daniel Smyser, Florence, S. C.; Maryland Medical College, Baltimore, 1912; member of the American Medical Association; served overseas during World War I; during World War II received congressional commendation for his services as regional director of Selective Service and procurement and assignment; colonel, medical reserve corps, U. S. Army, not on active duty; medical director and superintendent of Saunders Memorial Hospital; died February 15, aged 61, of coronary thrombosis.

Berton A. Souders, Cambridge, Ohio; Starling Medical College, Columbus, 1892; member of the American Medical Association; for many years member of the city school board; died March 3, aged 82, of cerebral hemorrhage.

Henry Tucker Spelman, Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1907; member of the American Medical Association; on the staffs of Kings County Hospital and the Norwegian Hospital, where he died March 3, aged 64, of ulcerative colitis and heart disease.

William H. Spiller, New York; University of Virginia Department of Medicine, Charlottesville, 1894; served in the Spanish-American War, Boxer Rebellion and Philippine Insurrection; formerly superintendent of Lying-in Hospital of the city of New York; at one time affiliated with New York Hospital, where he died February 23, aged 76, of hypertensive and arteriosclerotic cardiovascular disease.

Elizabeth Sweet, Redlands, Calif.; Cornell University Medical College New York, 1901; died March 9, aged 78, of chronic myocarditis.

Adolph Emil Voegelin ☉ Detroit; Medico-Chirurgical College of Philadelphia, 1916; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the American Heart Association; on the staff of Evangelical Deaconess Hospital; served during World War I; died February 22, aged 55, of myocardial infarction.

Allan Estes Walker ☉ Ferris, Texas; University of Texas School of Medicine, Galveston, 1933; served in British Ministry of Health from 1941 to 1942; officer during World War II; died March 3, aged 39, of thrombosis.

John Henry Wallinga, St. Paul; University of Minnesota Medical School, Minneapolis, 1919; secretary-treasurer of Samaritan Hospital; died in Belmond, Iowa, February 8, aged 58, in an automobile accident.

Ancrum Waring Jr., ☉ Sanford, Mich.; Medical College of the State of South Carolina, Charleston, 1942; member of the Medical Society of the State of Pennsylvania; served during World War II and received battle stars for Normandy, France, Northern France, Ardennes and a silver star; on the staff of the Midland (Mich.) Hospital, died in the Saginaw (Mich.) General Hospital March 7, aged 32, of injuries received when a motorcycle on which he was riding skidded.

Alfred Winslow Wheeler ☉ Norfolk, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1902; died February 28, aged 74, of acute coronary thrombosis.

Roland Thatcher White ☉ Orlando, Fla.; Chicago Homeopathic Medical College, 1886; died in the Florida Sanitarium and Hospital March 5, aged 84, of carcinoma of sigmoid with widespread metastases.

Eugene Maximilian Wiedenmann, Topeka, Kan.; Albert-Ludwigs-Universität Medizinische Fakultät, Freiburg, Baden, Germany, 1914; member of the American Medical Association and the American Psychiatric Association; assistant superintendent of Topeka State Hospital; died January 29, aged 59.

DIED WHILE IN MILITARY SERVICE

Thomas Hugh Spyker, Plain City, Ohio; Ohio State University College of Medicine, Columbus, 1946; interned at the Shreveport Charity Hospital in Shreveport, La.; began active duty as a first lieutenant in the medical corps, Army of the United States, on May 15, 1947; promoted to captain; died in Tilton General Hospital, Fort Dix, N. J., March 27, aged 26.

ITALY

(From Our Regular Correspondent)

FLORENCE, March 31, 1949.

Treatment of Diseases of the Liver

At the inauguration of the academic year of the Academy of Sciences of Ferrara, Professor Dogliotti, University of Turin, reported on "Treatment of Diseases of the Liver." The speaker discussed numerous important researches conducted in America, the results of which led to new problems in diagnosis and therapy of chronic hepatopathy with a cirrhotogenous background. The most convenient treatment may be considered as follows: The amount of protein should be increased in the diet and the glycide rate should be maintained at a high level. According to some authors the amount of lipids should be reduced, but according to others it may vary around a relatively high level. In general, a decisively increased amount of alimentary calories should be given—i. e., from 3,000 to more than 3,500, with the patient at rest. In addition, a generous increase in lipotropic substances, particularly choline and methionine, is required. This therapy does not exclude the use of other means which experience has shown effective in hepatopathy, such as hepatic extracts, vitamin B complex, vitamin C and corticoadrenal extracts. Favorable statistics furnished by American schools have been confirmed by the results obtained in the institute which is under the direction of the speaker. It is, however, too early to draw definite conclusions in this highly complex field, in which symptomatology and therapy are not very clear.

Association of Legal and Industrial Medicine

This association held a meeting in Naples under the chairmanship of Professor Palmieri. Sessa reported on his histologic research on rabbits and guinea pigs subjected to acute experimental intoxication with trinitrotoluene. The poison was administered by mouth on alternate days in doses of 0.20 to 0.50 Gm., with a total dose of 0.80 to 2 Gm. in four to eight days. Other animals were subjected to chronic intoxication with weekly doses of 0.01 Gm. to 0.02 Gm. with a total dose of 0.04 to 0.14 Gm. in twenty-four to fifty-two days.

On microscopic examination all the organs appeared injured, showing vascular congestion and occasional hemorrhages, and degenerative processes from turbid swelling to hyaline and fatty degeneration. The toxic process was characterized also by infiltration phenomena and mesenchymal reactions with noteworthy differences between the acute form, in which degenerative-necrotic elements prevailed and the chronic form, in which congestion and reaction were predominant.

During the various phases, changes were most evident in the kidney, liver and adrenal glands; next in order were those in the lungs, spleen, stomach and heart.

Prisco presented a report on cardiopathy. The statistics on the disabling and compensable morbidity from cardiopathy show among workmen an increase of about 2.65 per cent in the post-war period as compared with the prewar period. This increase, the speaker stated, was caused mostly by hardship among laborers, whose conditions of work had become particularly harassing. The speaker recommended a rigorous orientation concerning those suffering from cardiopathy, withdrawing them from heavy work which could disturb the circulatory compensation.

Graziani studied the oxygen consumption of the liver, of the kidney and of the bone marrow in the experimental intoxication by trinitrotoluene. Using Warburg's technic, he demonstrated a conspicuous increase in the consumption of oxygen by the liver and the bone marrow as compared with that in the control animals, while the respiratory quotient of the kidney was not

modified. As far as the liver is concerned, the catalyzing action of oxidation was called on to explain the excess of the consumption of oxygen; with regard to the bone marrow, the increased consumption may depend on the medullary hyperplasia which was observed on microscopic examination.

Peptic Ulcer and Electroshock

At the Association of Hospital Physicians of Genoa, Drs. Corbella and Piredda presented a preliminary note on the treatment of peptic gastroduodenal ulcer by means of electroshock.

The speakers recalled the first communications by Cushing in 1932, who had observed the occurrence of peptic ulcers as sequelae of surgical intervention on the base of the brain. There followed the investigations by Fulton, Hoff and Sheehan and by Roussy and Mossinger which resulted in the occurrence of bleeding ulcers in the gastroduodenal mucosa as sequelae of lesions produced in the diencephalon and in the prefrontal cortex of experimental animals.

The speakers recalled the symptoms of peptic gastroduodenal ulcer by which it resembles syndromes due to dysfunction of encephalic centers. They reported on electroshock therapy of 12 patients with gastroduodenal ulcer which had been demonstrated on roentgenologic examination. In all the subjects thus treated the painful symptoms and the dyspeptic disturbances subsided after the first treatment, and after the third treatment at the latest. The improvement was accompanied by a pronounced reduction of the free and combined hydrochloric acid. In a second report the speakers will present the late results of this therapeutic trial.

THE NETHERLANDS

(From Our Regular Correspondent)

AMSTERDAM, April 26, 1949.

Numerus Clausus or Numerus Fixus?

In the annual assembly of the Society of Friends of the University of Amsterdam the former President, Prof. J. J. van Loghem, gave a talk on the problem of the overcrowding of the universities. He treated this problem especially from the medical point of view. At this time there are 6,700 medical students—i. e., more than the total number of the medical profession in Holland. The medical faculties are overtaxed; consequently the quality of the medical training is in danger.

Professor van Loghem pointed out that *numerus clausus*—the university admits a limited number of students—is an attractive measure from the point of view of the professors and of the students admitted. On the other hand, it is an *unsocial measure*, as it does not reckon with the needs of the community. The speaker considered it preferable for the Government to fix each year a number representing the doctors expected to be wanted in the near future and to bring up the equipment of the faculties to this level. For this number Professor van Loghem coined the word *numerus fixus*, a conception intrinsically different from *numerus clausus*.

Low Mortality Figures

Professor René Sand, the Belgian pioneer of social medicine, considers the low mortality figures of his Dutch neighbor in *Bruxelles Médical*. As important causal factors he mentions the Dutch law on infectious diseases, the splendid nursing and educational work of the Green, White and White-Yellow Crosses, the organization of the national campaign against tuberculosis, the schools for social workers, the drinking water policy, the system of social insurance, the housing law and the nutrition of the population. Even in 1930 the children of the unemployed in Holland showed normal development.

This subject is also treated in the "Epidemiological and Vital Statistics Report of the World Health Organization." An article by Dr. Stowman on "The Declining Deathrate" characterizes

the Netherlands as "a class by itself, having the lowest general death rate in the world, in spite of its high birth rate which increases the age groups under 1 year having a high mortality risk. In 1947 the death rate was only 8.1 per 1,000, in 1948 7.4 per 1,000. It had never previously been considered possible to attain such low general death rates in a population of nearly ten millions without striking peculiarities in regard to economic or age constitution. An intensive investigation of this phenomenon and its possible underlying causes may well lead to useful results."

Two New Medical Journals

An editorial in the *Nederlandsch Tijdschrift voor Geneeskunde* gives a hearty welcome to two new periodicals, both of them quarterly journals: *Archivum Chirurgicum Neerlandicum* and *Documenta Neerlandica et Indonesica de Morbis tropicis*.

The former is published by a Collegium chirurgicum representing general surgery, urology, chest surgery, neurosurgery, plastic surgery and anesthesia. The board of editors is made up of four professors of surgery (Amsterdam, Leyden, Utrecht, Groningen), with Prof. I. Boerema as chairman and Dr. H. R. Bax (Arnhem) as secretary. The first number contains eight original articles, excellently illustrated, all in English.

The new *Quarterly Journal of Tropical Medicine and Hygiene* (this is its subtitle) is published by a special foundation, Prof. J. E. Dinger (Leyden) being the chairman of the managing committee. Prof. N. H. Swellengrebel (Amsterdam) is the chairman of the editorial board and Dr. Ch. W. F. Winckel is the editor.

In his introduction Professor Swellengrebel lays stress on the fact that, although the scientific achievements of the Dutch in the Netherlands Indies have been rather creditable as far as quality is concerned, it is to be regretted that they have neglected to render these achievements intelligible to their colleagues abroad. The appearance of this journal in English shows their intention of mending their ways in the future.

Centenary of the Medical Association

Next July the Netherlands Medical Association, which has its headquarters in Amsterdam, will celebrate the hundredth anniversary of its foundation. Eighty per cent of the medical profession are members of the association, constituting three subdivisions: the general practitioners, the specialists and the medical officers.

In Holland the ratio of physicians to the population is 89:100,000; the analogous numbers for the United States is 104. The celebration in July will last three days. Its program contains a two day scientific congress, an automobile rally for doctors on their way to Amsterdam, a reception by the municipality, a performance in the municipal theater, a medical-historical exhibition and many other entertainments. The board of the association expects many guests from all parts of the world.

BUENOS AIRES

(From Our Regular Correspondent)

Feb. 26, 1949.

Coca Chewing

The Society for Forensic Medicine and Toxicology in Buenos Aires voted unanimously that it is erroneous to admit that chewing coca leaves is useful or indispensable to life in the Andean altitudes. Medical observations have repeatedly shown that the white men who live at the same altitudes—with few exceptions—do not chew, with the consequence that they work much better. However, it must be recognized that the "coqueo" is an old and deeply rooted habit among the Andean Indians. Chewing coca leaves day after day and in the accustomed quantities results in chronic intoxication, which contributes much to the physical and mental degeneration of the Indian

race. The final goal must be the suppression of this habit, but the practical proceeding must be gradual, together with and during a definite improvement of the general living conditions for the native populations. It was noted that the resolution was voted on just at the moment when the United Nations are investigating the effect of chewing coca leaves on the inhabitants of certain regions of Latin America.

Thoracolumbar Sympathectomy in Hypertension

Drs. A. C. Taquini, A. Villamil, J. R. E. Suárez and J. M. González Fernández determined the blood volume in 5 hypertensive persons (3 of grade II, 2 of III) before and after thoracolumbar sympathectomy. They found an increase due to elevation of plasma and globular volume, but no significant modification of the extracellular liquid. In almost all cases the venous pressure did not vary. The circulation time remained unaltered in 3 cases and was prolonged in 2. Serum proteins remained within normal limits. Seventeen to one hundred and thirty-seven days after the second operation the minute volume was diminished in the 3 cases of degree II, the medium arterial pressure somewhat diminished, the total peripheral resistance increased and the cardiac output diminished. In the cases of degree III the minute volume was slightly augmented and the medium arterial pressure and peripheral resistance diminished, while the cardiac output remained practically unchanged. Later on, eight months to two years after the second operation, the 3 patients of degree II and 1 of III showed a similar picture: the minute volume was like that before the operation, and the medium pressure, the peripheral resistance and the cardiac output showed values like those before the operation or somewhat less. In the other case of degree III the minute volume and the cardiac output decreased below the preoperative level while the medium pressure and the peripheral resistance increased, the latter above preoperative figures.

Renal Lesions of Experimental Diabetes

Dr. V. G. Foglia, of the Houssay-Institute in Buenos Aires, together with Drs. R. E. Mancini and A. F. Cardozo, found that in extirpating 95 per cent of the pancreas of male and female rats, lesions appear only after two months, the glycemia remaining normal during this time; the same is the case after extirpation of more than 95 per cent (although hyperglycemia appears immediately). After the two months, the lesions are found in all of the rats; first an increase occurs in hyaline in the arterioles and the glomerular capillaries; later reticulin fibers appear in these vessels, and finally sclerosis. These glomerular lesions are diffuse and almost always serious, like those of diabetic patients, although without showing the hyaline masses.

Congress of Ophthalmology

The fourth National Congress of Ophthalmology was held in Mar del Plata. Among those present were Drs. Castroviejo and Conrad Berens of New York, A. R. Beese from Columbia, G. A. Hanson of Seattle; also specialists from France, Spain and Switzerland and delegates from many Latin American countries. There were four exhibitions: a scientific one by the four Argentine universities, one of social work, made by the Ministry of Public Health, an industrial one, and one of books and periodicals. The chairman was the titular professor for ophthalmology of the University of La Plata, Dr. Diego M. Argüello. The main subject was "Eye Tumors."

Causes of Death

In the city of Buenos Aires the figure for tuberculosis remained more or less the same: 2,735 in 1939 and 2,359 in 1947; that for cancer increased from 3,696 to 4,772 in 1947, but that for circulatory diseases increased steadily, from 5,698 in 1939 to 8,093 in 1947.

Brief Items

The third South American Congress of Neurosurgery will be held in Buenos Aires in March 1949. The main subjects will be surgical treatment of epilepsy; hemostasis in neurosurgery, and lobectomies. The president is Prof. Dr. Ramón Carrillo, Minister of Health, who is titular professor of neurosurgery in Buenos Aires.

The prize Mariano R. Castex of the National Academy of Medicine of Buenos Aires has been granted to Drs. Egidio S. Mazzei and Diego Taylor Gorostiaga y Elyeser Magalhaes, for their paper "El embolismo pulmonar en clínica, obstetricia y cirugía."

Correspondence

ANTABUS® FOR ALCOHOLISM

To the Editor:—In THE JOURNAL, April 2, page 954, there is a note on antabus® entitled "Antabus for Alcoholism," written by Dr. J. Murray Scott, medical director of Ayerst, McKenna & Harrison, Ltd.

We wish to call attention to the fact that the Monsanto Chemical Company has been manufacturing ethyl thiurad®, which is chemically tetraethyl thiuram disulfide and referred to as antabus® by Dr. Scott, as an item of commerce for the rubber industry for a number of years. The chemical is an old one, and we also wish to call attention to the fact that Monsanto has been supplying experimental quantities of highly purified tetraethyl thiuram disulfide to responsible ethical pharmaceutical houses capable of conducting qualified experiments on its value in the treatment of alcoholism.

We too have recognized the sociologic significance of this development and have carefully screened requests for this material. It is interesting to note that our medical people had observed for some time that workers on this compound, as well as other chemicals for the rubber industry, developed intolerance to alcohol. We are glad that the Danish workers have carried out their work showing the possible medical value in the treatment of alcoholism.

Since the articles referred to by Dr. Scott have appeared in the literature, however, we have been supplying qualified groups of investigators requesting the material for pharmacologic and clinical purposes.

HAL G. JOHNSON, PH.D.
Monsanto Chemical Co.
St. Louis.

MEDICINE IN THE PANAMA CANAL ZONE

To the Editor:—I have recently returned from a trip to the Canal Zone as a consultant to the Medical Department of the United States Army. I visited the Gorgas Hospital at Ancon, the Army Hospital at Fort Clayton, the Naval Hospital at Coco Solo and the Army Hospital at Colon.

I was afforded every opportunity to study the ophthalmic care given the patients, who included Army and Navy personnel, their dependents and the civilian employees of the government. In ten days, packed with activities, the over-all impression that I have carried away is that of excellent care given the patients, the high professional quality of the medical officers responsible for this care, and their hunger for professional shop talk.

There are weak spots to be sure; it could be scarcely otherwise when we consider that the Medical Department is understaffed at the moment and contains a number of men who have but recently completed their internships. In spite of these shortages, which are not too serious, there is evident a desire by the medical officers to give the best they can and to keep their professional acumen and keenness to a high level.

The facilities that are supplied the ophthalmologists are equal to those in many large universities and clinics and better than some. I was also impressed with the care that is taken of these necessary tools for good work.

Gorgas Hospital is, of course, the major installation. There is an enormous quantity of clinical material and an exciting variety of rare and unusual cases seldom seen outside of large charity hospitals. The opportunity to study and learn is endless, and most of the doctors have taken advantage of this chance. The atmosphere of the place is more like that of a well run medical school and hospital than any Government hospital with which I am familiar. The library is superb and contains not only an adequate number of up-to-date medical textbooks and systems, but a much larger variety of the current medical journals than are usually found in a general hospital. The good will of the commanding officer and his obvious desire to provide the best tools with which the doctors can do their jobs, unhampered by rules, regulations and red tape, are reflected throughout the institution. The result is, naturally, a happy and peaceful aura about the place that makes for contented work.

To draw together the civilian and Army doctors in this manner is a thrilling experience and cannot help being beneficial to the patients, the medical officers and the civilian consultants alike. The Medical Department of the Army is to be congratulated for adopting this fine program.

DERRICK VAIL, M.D., Chicago.

"LITTLE STROKES"

To the Editor:—Sophocles (C. 497 B. C.—405 or 406 B. C.) died suddenly and happily—probably from overexertion while giving a public reading of his tragedy "Antigone" or/and from overexcitement and joy when he was proclaimed victor in a contest, after reading the play or, as is altogether likely, from coronary thrombosis or a "little stroke" in his advanced old age, rather than from choking on an unripe grape!

Of interest, now, is the fact that Sophocles 2,400 years ago knew of, and wrote about, "little strokes." In his "Oedipus Tyrannus," 961, Sophocles says, "A little stroke puts aged bodies to sleep." Thus Walter C. Alvarez, of the Mayo Clinic, has recently revived the term "little stroke!"

I might add, too, that the old experienced navigator or pilot Phrontis, son of Onetor and Menelaus' boatman (Homer's Odyssey, Book III), dropped dead suddenly from overexertion with the steering oar of the moving ship (against the storming winds) within his hands. This sudden death was caused by coronary thrombosis or perhaps by Sophocles' "little stroke" rather than by Phoebus Apollo's gentle darts! Archangelus Piccolhomini (1525-1586) is of the opinion that "the obstruction of the little cord or vessel [or "nerve"] which goes to the heart, suddenly brought on, is the cause from which some persons go suddenly and unexpectedly out of this world."

HYMAN I. GOLDSTEIN, M.D., Camden, N. J.

INCIDENCE OF UNDULANT FEVER

To the Editor:—To determine the incidence of undulant fever in a private practice in the Stock Yards District of Chicago, we studied the blood samples of 100 consecutive patients between the months of June 1948 and January 1949. Of these 57 per cent were female and 43 per cent male, the ages varying from 19 to 63. All laboratory tests were done by the Division of Laboratories of the State of Illinois, Department of Public Health. Only one reaction was positive, and this in a dilution of 1 to 5,120, and 1 person had recovered from acute brucellosis five years previously.

FREDERICK STENN, M.D.
JOSEPH PLESTINA, M.T.
Chicago.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II.* Various Centers. June 20-22, Sept. 12-14. *Part III.* June, various centers. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY, INC. *Written.* Various Centers. July 15. *Oral.* Oct. 16-20. Sec., Dr. Curtiss B. Hickcox, 745 Fifth Ave., New York 27.

AMERICAN BOARD OF INTERNAL MEDICINE: *Oral.* Philadelphia, June 1-3. *Written.* Oct. 17. Asst. Sec.-Treas. Dr. W. A. Werrell, 1 Main St., Madison 3, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: *Oral.* Chicago, June 1949. Sec., Dr. W. J. German, 310 Cedar Street, New Haven, Conn.

AMERICAN BOARD OF OPHTHALMOLOGY: *Oral.* New York, June 11-15; St. Louis, Oct. 15-19; Boston, December. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY. *Part II.* New York City, Jan. 1950. Final date for filing application for Part II is Aug. 15. Address: Sec.-Treas., Dr. Harold A. Sofield, Room 1856, 122 S. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

AMERICAN BOARD OF PEDIATRICS: *Written.* Under local monitors, June 24. *Oral.* Cleveland, Sept. 16-18; New York City, Oct. 21-23; Chicago, Dec. 9-11. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

AMERICAN BOARD OF PHYSICAL MEDICINE. Philadelphia, June 4-5. Sec., Dr. R. L. Bennett, 30 N. Michigan Blvd., Chicago.

AMERICAN BOARD OF PLASTIC SURGERY: Examinations are given in June and November of each year in the home town of applicants. Sec.-Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY, INC. *Special Examination.* October. Place to be announced. Final date for filing application is July 15. December, New York City. Sec. Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF RADIOLOGY. Atlantic City, June 2-4. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF SURGERY: *Written.* Various Centers, October 26. Final date for filing application is July 1. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

AMERICAN BOARD OF UROLOGY: *Written.* December. *Oral and Clinical.* Chicago, Feb. 11-15. Final date for receipt of case histories is Sept. 1, 1949. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18, Minn.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: *Examination.* Montgomery, June 28-30. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

ARKANSAS: * *Little Rock*, June 9-10. Sec., Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 9-10. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

COLORADO: *Examination.* Denver, June 1-2. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

CONNECTICUT: New Haven, June 11. Exec. Asst., State Board of Healing Arts, Miss Mary G. Reynolds, 110 Whitney Ave., New Haven 10.

FLORIDA: *Examination.* Gainesville, June 11. Sec., Mr. M. W. Emmel, University of Florida, Gainesville.

MICHIGAN: *Examination.* Detroit and Ann Arbor, Oct. 14-15. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing 15.

MINNESOTA: *Minneapolis*, June 7-8. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis.

OREGON: Portland, June 18, Sept. 3 and Dec. 3. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

SOUTH DAKOTA: Vermillion, June 3-4. Dr. G. M. Evans, 310 E. 15th St., Yankton.

TENNESSEE: Memphis, July 8-9. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

WISCONSIN: Milwaukee, June 4, Sept. 24 and Dec. 3. Sec., Prof. W. H. Barber, Ripon College, Ripon.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Governmental Hospitals: Validity of Rules Fixing Standards for Practitioners Therein.—The plaintiff physician filed suit to restrain the defendant, Hamilton County Hospital, from interfering with, or discriminating against, him in his right to practice and perform his professional duties in the hospital. From a judgment for the physician, the hospital appealed to the appellate court of Indiana (81 N. E. [2d] 699; J. A. M. A. 139:251 [Jan. 22] 1949) and eventually to the Supreme Court of Indiana.

On Sept. 9, 1947, the board of trustees of the defendant hospital adopted certain rules regulating the qualifications which a physician must possess in order to practice medicine, surgery and obstetrics in the hospital. It was provided that "the Resident Active Medical Staff, which shall include all the physicians having an unlimited license to practice medicine in the state of Indiana and having membership in Hamilton County Professional organization of fully licensed physicians having the largest number of such physicians residing in Hamilton County" shall make up the membership of the Active Medical Staff of the hospital. "(d) 2. All appointments to the Staff and assignments to services shall be made by the Board of Trustees but only upon the recommendation of the Active Medical Staff. The Board of Trustees will either accept the recommendation of the medical staff or refer it back for further consideration with a statement of its reasons for such action: When final action has been taken by the governing body the superintendent will be authorized to transmit its decision to the candidate and to the chief of staff. . . ." Other rules provided that in order for a physician to practice in the hospital he either must be a member of this medical staff or must have a member of the medical staff associated with him in the treatment of his patient. A surgeon desiring to practice surgery in the hospital but not being a member of the surgical staff was required to be a member of the Active Medical Staff and, in addition, was required to "(b) have a certificate of internship showing one year's service as an intern in a hospital approved by the Council on Medical Education and hospitals of the American Medical Association. (c) In addition to intern training required under (b) he shall have had not less than three years of surgical training which meets the approval of the American College of Surgeons."

The plaintiff graduated from Indiana University School of Medicine in 1938 and practiced medicine in the state of Indiana from that time until June 1942, when he entered the army. He was placed on the army inactive list in January 1945 and became a resident of Noblesville, Ind., about January 1947. He was not a member of the Hamilton County Medical Society and was therefore denied membership on the Active Medical Staff of the defendant hospital. Furthermore, he did not have the intern training required to practice surgery in the hospital. He was therefore refused permission to practice medicine or surgery in the hospital.

To require membership of the plaintiff in the resident active medical staff of the defendant hospital before permitting him to practice in the hospital, said the Supreme Court, would be a reasonable requirement if such staff were provided for by reasonable rules of the hospital, or the Board of Health through its Council, as provided by the Indiana Statutes. The present rules, however, provide that the hospital can appoint new members to its staff only on recommendation of its staff. It would seem by this rule, the Supreme Court continued, that recommendation to membership may be rejected by the board, but that no one shall be made a member of the staff without such recommendation. This is an unreasonable requirement, as by it the hospital delegates to its staff a virtual veto of its right to perform one of its duties. By this arrangement the staff dictates what physicians may practice in the hospital. In so holding we are aware that courts of at least one other jurisdiction have approved of staff selection in public hospitals

by invitation from their staff. (*Selden v. City of Sterling*, 45 N. E. [2d] 329; J. A. M. A. 121:886 [March 13] 1943). With this holding we cannot agree.

It will be further noted, the Supreme Court continued, that by the involved rules, the plaintiff's right to practice in the hospital is not only conditioned on his being a member of the staff but also on his being a member of the Hamilton County Medical Society, an extragovernmental agency. His admission to this society depends entirely on the sole determination of the society. Whether he could ever become a member depends on conditions beyond his control. By this rule the hospital again delegates its power to determine what physicians may use its facilities. It amounts to a preference in favor of the society and a discrimination against those physicians who by choice or otherwise are not members of the same.

It is our conclusion, said the Supreme Court, that the complaint stated facts entitling the plaintiff to some relief; namely, the right to practice general medicine, excluding surgery, in the hospital, without being a member of the staff as here constituted, as membership on this staff can be increased only on recommendation of the staff and is limited to members of the Hamilton County Medical Society. It is our further opinion that the plaintiff is not qualified, under the valid portions of the rules now in force, to perform surgery in the hospital. We therefore affirm that portion of the judgment of the trial court which would prohibit the plaintiff from doing surgery and reverse that portion of the judgment which would prohibit the plaintiff from practicing medicine in the hospital other than surgery. Judgment was entered accordingly. *Hamilton County Hospital v. Andrews*, 84 N.E. (2d) 469 (Ind., 1949).

Medical Motion Pictures

FILM REVIEWS

Surgical Division of a Patent Ductus Arteriosus. 16 mm., color, silent, 625 feet (1 reel), showing time twenty-five minutes. Produced in 1948 by Mervin La Rue & Co., Chicago. Prepared by and procurable on loan from Willis J. Potts, M.D., The Children's Memorial Hospital, 707 Fullerton Avenue, Chicago 14.

The motion picture reviews briefly the essential signs and symptoms for a diagnosis of patent ductus arteriosus and emphasizes the diagnostic importance of a continuous "humming top" murmur. The surgical technic of division of a patent ductus by means of a new clamp is shown in detail. The basic feature of the clamp is embodied in rows of tiny teeth in the opposing jaws; when closed on the ductus, the teeth are embedded in the wall and will not slip. One clamp is placed on the aortic end of the ductus and another is placed on the pulmonary end. The ductus is cut and the stumps sutured with a double row of dekanatel® silk on a curved no. 9 atraumatic needle. The color photography ranges from fair to excellent. A few scenes are overexposed, and closer views of the author's method of clamping, dividing and suturing the patent ductus arteriosus would have improved this section of the picture. When considered in its entirety, the film is far superior to the average picture on this subject. It is highly recommended for showing to surgeons who are particularly interested in this type of surgery and residents working in a hospital where this work is being done.

Vaginal Hysterectomy. 16 mm., silent, color, 475 feet (1 reel), showing time seventeen minutes. Produced by Dwinell Grant Productions. Prepared in 1948 by and procurable on loan from Charles C. Weltzman, M.D., 847 Eastern Parkway, Brooklyn.

This motion picture attempts to demonstrate the author's operative technic in a vaginal hysterectomy with repair of cystocele and rectocele. Illustrative anatomic drawings are interspersed throughout the picture, some of which are misleading and do not give a clear concept of the topographic site. The operative field is unreasonably obscured by blood and the operator's hands, so that the steps of the operation are not easily discernible. This is a record type film having a minimum of teaching value. It is not recommended. The photography is poor to good.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Laboratory Evaluation of DDT Residual Effectiveness Against House Flies, *Musca Domestica*. R. W. Fay, A. J. Buckner and S. W. Simmons.—p. 877.

Streptomycin in Cultivation of *Endameba Histolytica*.

—In a previous study Spingarn and Edelman found that streptomycin prolonged the survival of cultures of trophozoites of *Endameba histolytica*. This effect was associated with bacterial inhibition. The favorable influence of streptomycin in prolonging the viability of trophozoites suggested that the drug might also prove valuable in starting cultures from cysts of *E. histolytica* found in stools. When they used a standard technic, their attempts to obtain cultures of trophozoites from stools containing cysts were usually failures. When streptomycin was added to the cultures at the time of inoculation with feces containing cysts, trophozoites were found with great regularity. The authors describe the method they used and the results obtained. They found that the addition of streptomycin in doses ranging from 1.0 to 10.0 mg. per cubic centimeter of serum-saline overlay favored the production of cultures of trophozoites from cysts of *E. histolytica* present in stools. The drug produced varying degrees of bacterial inhibition, and the growth of *Bacillus hominis* was suppressed. They believe that further experiments relating to the effect of antibiotics on *E. histolytica* may eventually provide a simple, reliable method for culturing trophozoites from cyst-containing stools. Their results confirm observations that there is considerable variability in the conditions required for the excystation and growth of *E. histolytica* in a particular specimen. By using a wide range of doses of streptomycin and, perhaps, penicillin as well, it may be possible to control the nature and density of bacterial flora in such a manner as to be able to culture *E. histolytica* cysts from

stools in every instance. This is an essential prerequisite for the use of a cultural method for diagnosis when microscopic studies reveal no or doubtful evidence of amebiasis.

Thrombophlebitis in Lower Extremity. J. E. Summers.—p. 315.

Propylthiouracil in Treatment of Angina Pectoris: Preliminary Report. R. L. Fisher and M. Zukerman.—p. 318.

Clinical Significance of Rumination.—Dambassis reports 9 cases of rumination in 4 multiparous women, 2 obese and 2 not, between the ages of 38 and 60, in 1 thin girl aged 22, in 1 obese man aged 45, in 2 boys aged 6 and 10 respectively and in 1 girl aged 9. The incidence was higher for women than for men. The hereditary factor was not present, although "ruminant families" have been described. Rumination is not a physiologic phenomenon. Hiatus hernia was present in 2 of the author's adult patients. Such conditions are favorable substrata for the development of rumination. The 3 children had a history suggestive of a low grade congenital circular muscle pyloric hypertrophy which commonly subsides in the first six months, sometimes leaving a certain degree of pylorospasm capable of causing squeezing contraction of the stomach musculature and elevation of the fundic pressure. In one of the middle-aged women aerophagia was the chief complaint, associated with temporary pylorospasm resulting in an increase of the fundic pressure. The girl aged 22 had an irritable colon; her case was considered among the reflex conditions in which anomalous impulses are brought about and result in a regional gastropasm or an incompetence of the cardia. In another middle-aged woman rumination was due to incompetence of the cardia, which had undergone an overrelaxation after having passed its culminant point of spasticity. The case of the obese man aged 45 was typical as that of a heavy and hasty eater and drinker who ruminated from his childhood, carrying over possibly a conditioned reflex probably caused by the infantile gluttony observed in some children. Treatment of rumination consists in reeducation of the patient and the appropriate therapy of the underlying cause. A bland diet is indicated. Coffee, tea and alcohol should be discarded. Some drugs such as phenobarbital, papaverine, calcium carbonate, bitter digestives and any glandular preparation are indicated.

"Silent" Dacryocystitis.—Theodore says that dacryocystitis is generally described as a chronic inflammation of the lacrimal sac due to stenosis of the nasolacrimal duct. The stenosis develops as a result of inflammation of the nasal mucosa extending by continuity to the mucous membrane of the nasolacrimal duct. A mucopurulent or purulent discharge is present, which flows into the conjunctival sac on pressure. Sometimes a mucocele develops. The condition known as acute dacryocystitis is more properly designated as acute peridacryocystitis. It occurs when the organisms present in chronic dacryocystitis

penetrate the submucous tissue and invade the wall of the sac itself. The "acute" inflammation is secondary to chronic dacryocystitis. These two types of inflammation of lacrimal sac appear to be the only ones generally accepted, but there exists a third type, an incipient, mild, low grade dacryocystitis in which obstruction is not important. The author reports 7 cases in which a mild type of dacryocystitis, usually mucoid in character, was the unsuspected cause of persistent conjunctivitis or of unexplained tearing. This "silent" type of dacryocystitis is overlooked if investigation of the tear passages is limited only to a determination of patency. If the lacrimal washings are collected and examined both clinically and bacteriologically, the finding of mucus or of pus containing pathogenic bacteria will indicate the presence of "silent" dacryocystitis. Once the diagnosis was established and treatment instituted, the conjunctivitis, which in almost every case of the present series had existed for months, subsided in a matter of weeks, recovery paralleling the clearing of the lacrimal washings. Experience suggests that this low grade type of mucous dacryocystitis is not uncommon and, if not recognized, may eventually lead to more obvious inflammatory changes in the lacrimal passages.

Treatment of Thyroiditis.—According to Crile there exist three main clinical types of thyroiditis: (1) the subacute (psendotuberculous or giant cell) variety, (2) struma lymphomatosa (Hashimoto's thyroiditis) and (3) Riedel's struma. In 2 cases of subacute thyroiditis and 2 cases of struma lymphomatosa proved by biopsy, roentgen therapy was followed by complete resolution of the palpably enlarged thyroid. Three patients with proved Riedel's struma were not benefited by roentgen therapy. Crile stresses that roentgen therapy is the treatment of choice for subacute thyroiditis, and thyroidectomy is rarely, if ever, indicated. When the diagnosis of struma lymphomatosa is made before operation, roentgen therapy should be given a trial, but if struma lymphomatosa is recognized at the time of operation a very conservative resection of both lobes of the thyroid is recommended. In Riedel's struma, roentgen therapy is of little or no value, and it is unwise, unnecessary and often dangerous to attempt to remove the entire lobe. If the onion-like concentric laminations in the fibrous tissue surrounding the central degenerating adenoma can be found, these avascular planes can be followed by blunt dissection and the core of the lobe shelled out without disturbing its capsule. After this procedure the symptoms are relieved and there is no further proliferation of fibrous tissue.

Lymphatic Spread of Carcinoma of Breast.—Monroe made a detailed pathologic study of 87 breast specimens removed at radical mastectomy. The location of the lymph nodes has been accurately charted and each of the lymph nodes examined microscopically. The study indicates that the greater the number of lymph nodes removed in the operative specimen, the greater the patient's chances for freedom from recurrence.

Mass Roentgen Examination.—Hall says that of 107,005 miniature roentgenograms taken, 1,726 disclosed signs suggestive of tuberculosis. Of these, 1,366 proved to be minimal lesions, 259 moderately advanced and 101 far advanced. The miniature roentgenogram is a tool that does not replace either the standard roentgenogram or the medical training and experience of the practitioner. The physician plays an all-important part in the mass survey program. He gets the results of this detection process, and the ultimate diagnosis of tuberculosis or of other pathologic conditions is up to him. A study of results of tuberculosis control programs in the past indicates that much time and energy probably have been devoted to the wrong population groups. Tuberculosis is not a disease found commonly in children. The mass survey also indicates that the prevalence of tuberculosis increases with age. The survey should not be conducted in grade schools, but should be concentrated among industrial and other general adult population groups. We can protect children from tuberculosis by detecting tuberculosis among the parents. An adult population free of tuberculosis will result in a young generation free of infection. Tuberculosis is spread almost entirely by adults. If all tuber-

culous adults could be found, isolated, treated and the disease arrested, the next generation would have practically no source of infection, and tuberculosis would become a relatively infrequent disease.

Circulin, an Antibiotic.—McLeod says that a new antibiotic has been obtained from broth cultures of a mucoid variant of *Bacillus circulans*. This substance is active against both gram-positive and gram-negative bacteria and against fungi. It is bactericidal as well as bacteriostatic, and the activity is not appreciably reduced in the presence of blood serum. Circulin is hemolytic and extremely toxic. Although it is unsuitable for parenteral administration, limited trials indicate that it has possible value in the treatment of bacterial and fungous infections of the skin. Efforts are now being made to reduce the toxicity of circulin.

Peritoneal Irrigation in Oliguria Caused by Transfusion.—McCaffrey reports a woman, aged 40, in whom renal insufficiency due to a transfusion reaction developed. Caudal analgesia and renal decapsulation failed to alter the progress

of the uremic syndrome, but peritoneal irrigation effected an immediate dramatic lowering of the blood metabolites with great clinical improvement in the patient. The return of renal function is not believed due directly to the use of peritoneal lavage but it is felt that the lowering of the blood metabolites in the short span of eighty-two hours of lavage halted the progress of the uremia for a sufficient period to enable the kidneys to regain their normal functions. The method is recommended as worthy of consideration in any case of uremia that threatens to have a fatal outcome.

Experimental Pulmonary Embolism.—Holden and his co-workers attempted to determine whether or not pulmonopulmonary, pulmonovaginal depressor and pulmonocoronary reflexes contributed to the death of animals subjected to massive pulmonary embolism. Pulmonary embolism closely simulating that occurring in human beings was produced experimentally in dogs. No evidence was obtained from these experiments to support the supposition that pulmonopulmonary, pulmonocoronary or pulmonovaginal depressor reflexes contribute to the death of dogs after massive pulmonary embolism. It is suggested as a result of this work that the use of papaverine in the treatment of massive pulmonary embolism is without benefit and may be harmful. The constant absence of postembolic thrombosis in the pulmonary arteries of the heparinized animals suggests that the early intravenous administration of heparin to patients may be of great value.

Lateral "Aberrant" Thyroid Tumors.—Warren and Feldman feel that in regard to the tumors of thyroid tissue in the lateral regions of the neck three possibilities have to be considered: (1) lateral thyroid tumors originate in thyroid tissue which is separated from the thyroid gland by defective embryogenesis and in the majority of cases metastasize to the thyroid; (2) tumors in thyroid and aberrant thyroid tissue represent multicentric neoplastic growth in a single type of embryonal rest; (3) they are early metastases from a tumor of the thyroid gland and become clinically apparent before the tumor of the thyroid manifests itself. The authors aimed to determine what features can be considered as evidence for one or another mode of origin. They analyzed the lateral thyroid tumors received in the laboratory of the New England Deaconess Hospital over a period of nineteen years. There were 63 cases diagnosed as lateral aberrant thyroid tumor among approximately 20,000 surgically removed thyroids. In 57 of these the clinical diagnosis of lateral thyroid tumor was confirmed by histologic examination. In 49 of the 57 cases there was an associated thyroid cancer. In the remaining 8 cases the thyroid was not received in the laboratory, either because it was removed elsewhere or because it was regarded as uninvolved. The histology of the tumor in the thyroid and in the lateral masses of the neck was identical in all but 1 instance. In 40 of the 57 cases the lateral tumors were found to be metastases to cervical lymph nodes. In the remaining 17 cases there was no microscopic evidence that the lateral tumors were either metastatic or derived from embryonal rests. Thus the data indicate that most if not all lateral thyroid tumors of the neck are metastases from cancers of the thyroid. These neoplasms tend to occur in a younger age group than does cancer or thyroid disease. The presenting symptom is usually only a swelling or nodule in the neck. The disease often recurs locally unless completely eradicated. Follow-up observations must be made over decades rather than years.

Skin Grafting in Radical Mastectomy.—This study by Conway and Neumann is based on 255 patients on whom radical mastectomy was performed for carcinoma of the breast. The shortest follow-up was five years. Special attention has been given to the relation of the use of a skin graft to local recurrence. In 188 cases in which a graft was employed, there were 40 instances of local recurrence (21 per cent), whereas in 67 cases of closure without a graft, there were 4 instances of local recurrence (6 per cent). However, the size of the tumor at the time of operation had an important bearing on the incidence of local recurrence. In the smallest tumors the rate of local recurrence was 4 per cent, whereas in the largest tumors the rate of recurrence was nearly 50 per cent. Local recurrence had a bearing on the length of survival. In the 125 patients surviving more than five years, local recurrence developed in 1.6 per cent, whereas in the 130 patients surviving less than five years the rate of recurrence was 32 per cent. Of the 40 instances of local recurrence following grafting, 27 appeared as solitary nodules in the immediate vicinity of the graft whereas only 13 appeared within the grafted area or as multiple metastases both surrounding and within the grafted area. This situation gives rise to the thought that more radical excision of skin might give further protection against local recurrence. Since the rate of local recurrence seems to be closely related to the size of tumor at the time of operation, it seems likely that local recurrence in the form of solitary nodules outside the area of grafting is related to insufficient removal of skin. The suggestion is therefore made that the excision of skin in radical mastectomy be more radical. With the improved methods of skin grafting now available, it seems indefensible that surgeons should not remove a truly wide area of skin at the time that radical mastectomy for carcinoma is carried out. The larger the tumor the greater the need for wide excision of skin.

Effect of Intravenous Dextrose and Amino Acids on Urinary Output.—Lockhart and Elman gave one hundred and four timed and controlled 1 liter injections of dextrose solutions intravenously to 32 selected adults. These subjects were patients in the general surgical wards who were either awaiting plastic or other elective procedures or had had their operation previously and were about to be discharged. The dextrose solu-

tions were administered intravenously in the usual amount (1 liter) at rates ranging from 0.35 to 3.1 Gm. per kilogram per hour. The glycosuria resulting from each injection and the degree of diuresis were measured. The following solutions were utilized: 5 per cent dextrose in water; 5 per cent dextrose in isotonic sodium chloride solution; 10 per cent dextrose in water; 10 per cent dextrose in isotonic sodium chloride solution; 5 per cent amigen® in 5 per cent dextrose; 5 per cent pure amino acids in 5 per cent dextrose; 15 per cent dextrose in water; 15 per cent dextrose in 5 per cent amigen®; 15 per cent dextrose in 5 per cent pure amino acids; isotonic sodium chloride solution. The maximum speed of injection of dextrose without production of glycosuria was found to approximate 0.5 Gm. per kilogram per hour. This is much lower than the rate of 0.85 Gm. per kilogram per hour found by Woodyatt and his co-workers. In clinical usage this slower rate of injection should be used when dextrose is administered intravenously even to patients in a good state of health, in order to avoid glycosuria and associated diuresis. Urinary output was considerably reduced when isotonic sodium chloride was present in the intravenous solution. Higher concentrations of dextrose tended to produce more diuresis than lower concentrations, and the amount of diuresis tended to increase with the increased rates of administration. Evidence was obtained that the addition of hydrolyzed protein (amigen®) or pure amino acids to the dextrose solutions increased the rate of utilization of dextrose by the tissues. This was shown by a lower blood sugar level and less glycosuria when amino acids were present than when solutions of dextrose alone were given at the same rate.

Influenza Virus Vaccine and Prevention of Colds.—The purpose of this study by Blanton and Sutphin was to determine whether or not in a selected civilian group a stock influenza virus vaccine of types A and B could influence the number and severity of the whole group of acute infections of the upper respiratory tract. Approximately 1,400 industrial workers and college students in Richmond were given 1 cc. of influenza virus vaccine in the fall of 1946. An additional 583 male employees of the same company received the vaccine elsewhere in the state. No epidemic of influenza occurred in Virginia during the period of study. No convincing evidence was obtained to show that the common cold is influenced by this type of vaccine.

Duodenal Spread of Pyloric Carcinoma.—After reviewing the literature on duodenal immunity from cancerous permeation, Fodden presents his investigations on the frequency and manner of spread of the neoplasm into the first part of the duodenum in 50 cases of pyloric carcinoma. Sixteen cases showed that such an invasion of the duodenum had occurred, the invasion being more widespread and destructive in necropsy cases than in surgical cases. In 5 out of the 9 surgical specimens showing such duodenal involvement, cancer cell groups were seen at the edge of the duodenal resection. Progression of the growth occurred mainly through the lymphatics of the duodenal wall, and demonstrated an anastomosis between the pyloric lymphatic plexuses and those of the first part of the duodenum. In a smaller proportion of cases the pyloric neoplasm invaded the duodenal tissues directly. It was felt that the familiar macroscopic check to pyloric cancers at the duodenum was due to the duodenal mucous membrane and the layer of Brunner glands. Microscopically, these were the only tissues which appeared to resist the spread and destructive effects of the growth.

Diagnosis of Intestinal Obstruction by Direct Radiography.—Middlemiss investigated the part which radiology can play as a diagnostic measure in 151 cases of suspected mechanical intestinal obstruction and in 37 cases of postoperative distension. The distended bowel contains gas and fluid, and these two static elements separate to form fluid levels in the most dependent loops of the bowel. Gas shadows appear on roentgenograms as less opaque shadows than those of neighboring tissues or fluids. Roentgenographic technic therefore must be directed toward the demonstration and utilization of these gas shadows as a contrast medium. A routine technic of a supine and an erect roentgenogram of the abdomen using a posteroanterior projection where possible and using intensifying screens and a moving grid at an anode-film distance of 36 to 48 inches (91.4 to 121.9 cm.) is recommended. The appearances of mechanical obstruction of the bowel are as follows: stasis within the bowel as shown by the presence of fluid levels, and distension of bowel by gas. The site of the obstruction can be localized as being distal to the most distal part of the distended bowel. Thus obstructions of the small bowel can be

labeled high, mid or low obstructions. Obstructions of the large bowel can usually be localized more accurately; care must be taken not to diagnose an obstruction of the large bowel with an incompetent ileocecal valve as an obstruction of the small bowel. Volvulus, intussusception and perforation of a gas-containing viscus are conditions which may produce roentgenologic signs recognizable on scout survey films. Negative roentgen findings must be evaluated with reserve. Mechanical obstruction may still exist in the absence of positive roentgenologic evidence. It is of utmost importance to differentiate between adynamic obstruction, localized and generalized, and mechanical obstructions, as the early recognition of the latter in postoperative cases may be a life-saving measure. Closest liaison between the clinician and the radiologist is emphasized.

- Lymphadenoma of Salivary Glands. B. P. Tribedi and A. R. Roy.—p. 367.

Extrapleural Filling with Lucite® Spheres.—Bordia shows that the use of extrapleural filling or plugging is not a new procedure and that with the advent of antibiotics this operation is again being used more frequently. In the search for a suitable substance for extrapleural filling the plastic methyl methacrylate (Lucite®) has been tried; since the solid substance proved too heavy, hollow spheres have been used. The author cites American workers who have used this filling substance and discusses the indications and contraindications to its use. He outlines the technic of the operation and the postoperative course. This method may be extremely useful in the management of tuberculosis in India. The ease with which it can be undertaken makes it suitable for the conditions there. He believes it will replace thoracoplasty in the vast majority of cases.

Sensitizing Drug Against Alcoholism.—Martensen-Larsen points out that the discovery by Hald and Jacobsen, that the intake of tetraethylthiuramdisulfide (Antabuse®) sensitizes the organism to even moderate doses of alcohol, makes it possible to develop a medical treatment for alcoholism. Concurrently with the examination of the pharmacologic effects of this substance, Martensen-Larsen has studied the clinical effects of the drug on alcoholic addicts. From December 1947 to May 1948, 83 patients have been treated. So far no harmful systemic effects on liver, heart, kidney or blood-forming organs have been observed; nor have any untoward side effects been noted. The treatment has produced satisfactory results in 74 of the patients. The remaining 9 have lacked interest in the treatment and have refused to continue it.

Hypertrophy of Pylorus in Adult.—Barrie and Anderson report the case of a woman, aged 27, with two weeks' history of constant circumumbilical pain intense enough to keep her awake at night and of pain and a feeling of distension between the breasts immediately after taking food. She had vomited after every meal, and this had relieved the pain between the breasts. She had lost weight. Four years previously she had had a similar but less severe attack associated with melena, but the symptoms had lasted a fortnight. Her appetite had been good between these two attacks, but eggs, pastry and bacon caused indigestion. Roentgenoscopy after a barium meal indicated hypertrophy of the prepylorus, for which a partial gastrectomy

was performed. The surgical specimen showed concentric hypertrophy of the muscular coat of the stomach, pylorus and duodenum, with massive eosinophil infiltration of the pylorus and peculiar para-arterial giant cell follicles. The evidence suggests that this is an example of a true organic intestinal allergic reaction. The woman did not tolerate certain foods well; she had constant blood eosinophilia and a localized tissue eosinophilia of the pylorus. There were giant cell follicles in the pylorus which closely resembled follicles found in the heart muscle of patients who have become sensitive to neoarsphenamine.

*Diagnosis and Treatment of Low Backache. M. G. Good.—p. 496.

Low Backache.—Good differentiates backache into a symptomatic or secondary and a primary form. The secondary form occurs as a symptom of organic illness in infectious diseases such as smallpox, influenza or typhoid, and in renal or gynecologic disorders. Primary backache may be due to morbid conditions in (1) muscles, ligaments and fascia; (2) joints and bones, and (3) nerves. Experiences in the British Army with several hundred cases seem to justify the conclusion that a myalgia of lumbar, gluteal and other muscles is responsible for most cases of low backache. The main symptom of this form of myalgia is pain of two kinds—a dull, deep kind, which cannot be localized properly and a superficial type which is localized. The pain is aggravated by contraction and relieved by relaxation of the affected muscles. Sometimes it increases during sleep and awakens the patient. The objective signs center around muscular areas termed "myalgic spots" which, as a rule, are harder to the touch than the surrounding parts, but nodules are absent. Pressure on a myalgic spot produces a severe pain. The author discusses the lumbar, gluteal, lumbogluteal and dorsal forms of myalgia. A salt-poor vegetarian diet has a beneficial effect on myalgias and infra-red ray treatment followed by strictly local massage gives satisfactory results provided it is applied to the myalgic areas and not to areas of referred pain. The disadvantages are that massage of myalgic spots is painful and up to several months are often necessary for complete relief. A more rapid and effective relief can be obtained by injection of 1 to 2 cc. of 1 per cent procaine into each myalgic spot. Failure of this local anesthesia is due to a faulty technic; the injections have to be made into accurately located myalgic spots.

Thiouracil versus Surgery.—One hundred patients treated with thiouracil since 1944, 50 of whom ceased medication, were analyzed by Fischmann and Fischman with a view to obtaining data regarding the relative merits of surgery and thiouracil in the treatment of thyrotoxicosis. There is no justification for treating nodular goiter with thiouracil, since the relapse frequency is seven times higher after this than after surgical treatment. Thyroidectomy in nodular goiter permanently abolishes increased thyroid size and also prevents malignancy. In diffuse goiter, surgery and thiouracil have no apparent advantages over one another in regard to applicability, efficiency, unfavorable reactions and the ophthalmopathy of thyrotoxicosis. Treatment with thiouracil is slightly superior with regard to the duration of incapacity and the mortality rate. It does not induce permanent myxedema and avoids the disfigurement caused by the scar. Surgery is superior with regard to reducing thyroid

size. It seems that as an alternative to surgery, thiouracil and its allies deserve further trial in the treatment of diffuse toxic goiter. In nodular goiter surgery is the treatment of choice. Radioactive iodine seems by far the most effective of the three available methods of treating toxic goiter. Some authors have called attention to pathologic potentialities involved and have suggested that the therapeutic trial of radioactive isotopes should be limited to cancer.

*Etiology of Constrictive Pericarditis, with Special Reference to Tuberculous Pericarditis, Together with Note on Polyserositis. G. W. S. Andrews, G. W. Pickering and T. H. Sellers.—p. 291.

Causation of Constrictive Pericarditis.—Andrews and his co-workers report 11 cases of chronic constrictive pericarditis in 6 men and 5 women between the ages of 18 and 63. Constrictive pericarditis is a clinical entity which should be differentiated from other forms of adherent pericardium and from polyserositis. Ascites and edema are its chief symptoms; venous congestion and enlarged liver are the chief physical observations. The heart itself exhibits little abnormality. The pericardium is thick and fibrous, and usually reveals no clue as to the nature of the causative disease. Constrictive pericarditis is not due to antecedent acute pericarditis arising from rheumatism, uremia, myocardial infarction or malignant metastasis. During a seven year period all cases of other forms of acute pericarditis—namely, 18 cases of acute tuberculous pericarditis, 7 cases of acute septic pericarditis and 1 case of so-called idiopathic pericarditis—have been studied. In 16 of the 18 patients with acute tuberculous pericarditis, 14 male and 4 female patients between the ages of 4 and 49 years, 4 without and 14 with tuberculosis of other serous cavities (polyserositis), constrictive pericarditis developed. Pericardiectomy was performed in 9 of these patients, of whom 3 died; the remaining 6 improved greatly. The pericardium showed a healed scar in 1 and active tuberculosis in 7 seven months to five and a half years from the onset. Pericardiectomy in the presence of active tuberculosis does not seem to increase the liability to dissemination of the disease. Of 7 patients with acute septic pericarditis, 5 died in the acute phase. In neither of the 2 survivors did constrictive pericarditis develop. In the 1 patient with so-called idiopathic pericarditis constrictive pericarditis did not develop. In Great Britain most cases of constrictive pericarditis are due to antecedent acute tuberculous pericarditis. It is the rule for constrictive pericarditis to develop as tuberculous pericarditis. No other form of acute pericarditis has been observed to heal in this way. None of the 11 patients with chronic constrictive pericarditis gave a history of past acute pericarditis. Of all the forms of acute pericarditis, that due to tuberculosis is the most likely to be overlooked.

Curare: Report. G. G. Henderson.—p. 770.

Postural Proteinuria.—Bull and his associates point out that it has long been known that benign forms of proteinuria exist, and it is almost generally agreed that the commonest of these are the postural proteinurias. In earlier investigations one of the authors had demonstrated that the lordotic posture induces and the kyphotic posture prevents proteinuria. The application of a firm binder to the abdomen prevents the proteinuria ordinarily induced by the lordotic posture. Postural proteinuria is accompanied by an increase in the output of all

the formed elements in the urine, and clearance studies reveal a fall in effective renal blood flow and glomerular filtration rate and a rise in the filtration fraction. The protein can be found in the urine from both kidneys. There is a delay in the foot to tongue circulation time and a rise in pressure in the inferior vena cava in strict association with the proteinuria. Proteinuria can be induced in subjects with large and easily palpable livers by rotating the liver manually so that its anterior surface moves inferiorly. In this investigation the authors are concerned with the incidence of postural proteinuria and with whether postural proteinuria is more common in certain constitutional types. Three hundred and seven boys and youths between the ages of 6 and 20 years, 123 girls between the ages of 6 and 13 years, 50 medical students between 20 and 30 years of age and 50 male subjects over the age of 50 years were investigated. It was found that the incidence of postural proteinuria rose from approximately 1:3 in the 6 to 9 year age group to approximately 3:4 in the 14 to 16 year age group and then decreased to about 1:10 in older men. There was no correlation between postural proteinuria and the state of nutrition.

- *Variations in Size and Shape of Eye. S. Stenström.—p. 559.

Conjunctival Lipoma in Three Generations.—Conjunctival tumors such as lipomas are comparatively rare. Sæbø reports 3 patients with such tumors. The patients belonged to three generations of the same family, indicating a hereditary anomaly. The first case concerned a woman, aged 51; a growth was observed in her right eye after birth, but this growth never caused any inconvenience. There was slight bulging of the lateral part of the superior palpebra. About 5 mm. outside the corneoscleral limbus there was a yellowish white vertical conjunctival fold. When the eye was wide open a yellowish white tumor was seen extending backward from the conjunctival fold. Its thickness was about 5 mm., and the consistency soft and elastic. The tumor was firmly adherent to the bulbar conjunctiva, but freely movable against the underlying sclera. The daughter of this woman, aged 22, had a similar congenital growth. According to the mother's information her father had a similar tumor in his right eye. Her father is now dead, but a photograph shows a fold in his right eye, similar to that of the two others.

Variations in Size and Shape of Eye.—Stenström points out that for a satisfactory roentgenographic localization of a foreign body in the eye, the first essential is to ascertain whether the foreign body lies within or outside the bulb. In certain cases this can be done only if the size of the bulb is known. In earlier procedure, consideration could not be paid to this matter, as no method was available for measuring the length of the bulb in vivo. Rushton's procedure makes this possible. Stenström, with the aid of Rushton's method, has made longitudinal measurements of a large number of eyes, at the same time measuring the horizontal equatorial diameter according to the method of Berg. The results thus obtained are reported. The author stresses that the size and shape of the eye show such decided variations that an eye of average size cannot be reckoned with when foreign bodies have to be localized in the orbit. Not even if the refraction of the eye is known can one work with a schematic value of the axial length. Where the greatest precision is required, and especially in the borderline cases in which the foreign body lies close to the posterior pole of the eye, one should, if possible, measure the length and equatorial diameter of the eye. If this is impracticable, the great variations in the size of the eye should be taken into account.

Threatened Cardiac Infarction.—Holzmänn reports 4 typical cases of acute severe angina pectoris in 3 men between the ages of 38 and 52 and in a woman aged 53. This syndrome is characterized by repeated attacks of angina pectoris with increasing frequency and intensity which first results from exertion, but later may occur while at rest. The duration of the attack may exceed the limit of ten to fifteen minutes and there may be no response to the usual dose of glyceryl trinitrate. In the author's cases the syndrome of acute severe angina pectoris was a prodrome of cardiac infarction. The electrocardiogram of 2 of these patients showed peculiar changes with a lowering of the ST segment which were interpreted as protracted coronary insufficiency, being considered as a prodromal phase of the infarction. In 1 case the attempt was made to prevent the threatened coronary thrombosis by combined treatment with intravenous injections of heparin and dicumarol® orally. An infarction of the posterior wall occurred with mild clinical symptoms, suggesting that the prophylactic treatment was instituted too late. Treatment with heparin and dicumarol® should be instituted immediately in cases of acute severe angina pectoris and should be combined with vasodilators such as aminophylline. In the presence of signs of inflammation additional administration of penicillin is recommended.

- *Use of Methylthiouracil During Pregnancy and Lactation. W. Bickenbach, M. Hess and A. Loeser.—p. 640.

Use of Methylthiouracil During Pregnancy and Lactation.—Bickenbach and his associates found in experiments on rats that when mother animals were given methylthiouracil before mating and during part or even the whole length of gestation the development of the young animals at birth showed no visible changes. However, when methylthiouracil medication of the mother animal was continued during lactation, the nursing young commenced to show signs of cretinism beginning with about the second week of life. The symptoms of cretinism proved to be reversible, for when the young were separated from their mother the signs of cretinism subsided, but the young were extremely susceptible and few survived separation from the mother. Signs of cretinism and high death rate were observed also when the mother animal was given methylthiouracil only during the period of lactation. This indicates that the substance is excreted in the milk of rats. The authors warn that the fact that rats remain unimpaired by methylthiouracil during gestation cannot be applied to human conditions, especially since the placental mechanism in human subjects differs from that in rats.

- *Oral Administration of Penicillin in Infants. B. Z. Verbin.—p. 65.
- BCG Vaccination Against Tuberculosis. A. Zifrony.—p. 68.

Penicillin by Mouth for Infants with Diarrhea.—Verbin gave penicillin by mouth to 95 infants with acute diarrhea. Ninety of these recovered and 5 died. The author gained the impression that this method of administration is effective in purely intestinal disturbances as well as in parenteral complications. He was able to prove in experiments that penicillin is

absorbed in therapeutically active amounts after oral administration to infants. Laboratory tests have shown that the acidity of the infantile stomach is lower than that of the adult stomach, the gastric juice of adults exerting a destructive effect on penicillin, whereas in infants this is not the case. The intestinal flora of infants with diarrhea is chiefly gram positive and the administration of penicillin changes it to gram negative.

*Etiologic Conditions in Pulmonary Cancer. W. F. Wassink.—p. 3732.

Emotional Factors in Essential Hypertension.—According to Groen and Reisel it is well known that the blood pressure of normal persons fluctuates considerably under the influence of emotions, and in patients with essential hypertension this seems to be so to an even greater extent. Frequently patients themselves ascribe an intensification of their hypertension to some emotional annoyance. The authors tried to determine whether the character structure of these patients is such that they are predisposed to emotional conflicts and also whether the onset or exacerbation of the hypertension was preceded by an emotional upset. They obtained their data from 50 patients with essential hypertension whose ages varied between 18 and 60 years. They found that these patients are usually active, hard working persons with a tendency to perfectionism. They are inclined to lead and to dominate. They are not satisfied with themselves, and while outwardly they may appear self assured, inwardly they are not. Many make great efforts to adjust themselves to their surroundings; they have a great need to be loved and appreciated. One of the most fundamental characteristics of these patients is a strong destructive aggressiveness, and this combined with the need for love and appreciation makes for chronic conflict situations.

Pulmonary Cancer.—Comparing the occupations of 143 patients with cancer of the lung and trachea with the occupations of hundreds of other patients with cancers in which occupation seems to be without significance, Wassink gained the impression of a high incidence of cancer of lung and larynx among brain workers and a low incidence of this type of cancer among agricultural workers. Further investigations suggested that excessive smoking and remaining for long periods in rooms in which the air is laden with tobacco smoke is one of the most important exogenous causal factors in cancer of the lung.

Temperature and Pulse in Acute Appendicitis Illustrated by 2,250 Cases.—Dahl-Iversen and Sørensen found agreement between the temperature of children and adults in acute appendicitis. According to their material the clinical value of temperature and pulse rate in acute appendicitis is slight. There is no temperature or pulse rate, they assert, which is characteristic of appendicitis, and differential diagnosis with respect to febrile disorders with similar symptoms must be made

along other lines. There is no typical temperature or pulse rate for the different types of appendicitis. Temperature and pulse also are not important in evaluation of the gravity of a case. Normal or slightly elevated values do not exclude a grave case. In cases where appendicitis is suspected the history and especially the abdominal findings should hold the central place in diagnostic consideration. In a given case a rise in temperature and pulse points to aggravation of the pathologic process.

Miliary Tuberculosis Treated with Para-Aminosalicylic Acid (PAS) and with Para-Aminosalicylic Acid and Streptomycin.—Carstensen and Söderhjelm say that while both para-aminosalicylic acid and streptomycin possess high tuberculostatic activity, with streptomycin apparently somewhat superior, streptomycin because of its toxic properties has shown itself unsuited for use in prolonged treatment. In experimental tuberculosis in mice better therapeutic results have been attained by combination therapy with para-aminosalicylic acid and streptomycin than with either agent alone. Three cases of typical miliary tuberculosis are published. In the first, with death from meningitis, there was roentgenologic regression of the miliary pulmonary changes in the lungs after six months' treatment with para-aminosalicylic acid, and necropsy revealed healing of miliary foci in lungs, liver, spleen and kidneys. In the next case, with decided changes in lungs and ocular fundus, healing has apparently occurred after combination therapy; para-aminosalicylic acid was given almost constantly for ten months, streptomycin for two periods of twenty-one and eighteen days respectively (total amount, 32.7 Gm. and 18 Gm. respectively). In the third instance the results are promising after combination therapy with para-aminosalicylic acid for three months and streptomycin for eleven days (total amount, 20.4 Gm.). The authors advocate prolonged treatment of recent tuberculous manifestations with para-aminosalicylic acid, in grave conditions supplemented with streptomycin for shorter periods.

*Macrocytic Anemia Associated with Cirrhosis of Liver (Pathogenesis and Treatment). L. Braier.—p. 293.

Macrocytic Anemia in Cirrhosis of Liver.—According to Braier, Laënnec's cirrhosis of the liver is frequently associated with mild macrocytic anemia, which differs from that associated with Biermer's disease because of the absence of megalocytes and of anisopoikilocytosis. It is an "isomacrocytosis" in contrast to the anisomacrocytosis associated with Biermer's disease. The concept according to which macrocytic anemia associated with Laënnec's cirrhosis of the liver may be caused by an insufficient storage of the antianemic factor—i. e., by severe lesions of the hepatic parenchyma—is erroneous. Eppinger's and Naegeli's concepts of hypersplenism may explain certain types of anemia in cirrhotic patients, but in the majority of cases the macrocytic anemia like the cirrhosis itself depends on complex and only partly known disturbances of nutrition and of metabolism. The macrocytic anemia in cirrhosis is often resistant to antianemic agents, such as liver extract, blood transfusions and iron. The author treated 6 patients with large doses of folic acid combined with very large doses of concentrated extract of liver by mouth, and 5 patients with 2 Gm. of synthetic methionine daily by mouth for several weeks and even for several months. Definitely favorable results could not be obtained in any of these cases, not even in those patients whose general clinical condition improved under a dietary regimen devised for the protection of the liver by containing lipotropic agents and brewer's yeast. Ten patients with Laënnec's cirrhosis, 1 of them with macrocytic anemia, were given 5 Gm. of choline daily by mouth for several weeks; although choline did not exert any disadvantageous effect on the blood picture of the patients, the drug was ineffective in the case of the patient with macrocytic anemia.

Book Notices

The Renal Origin of Hypertension. By Harry Goldblatt, M.D., C.M., Director, Institute for Medical Research, Cedars of Lebanon Hospital, Los Angeles. Publication Number 14, American Lecture Series. A Monograph in American Lectures in Pathology, edited by Paul R. Cannon, M.D., Professor of Pathology, University of Chicago, Chicago. Fabrikoid. Price, \$2.75. Pp. 126, with 38 illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Illinois, 1948.

This monograph constitutes an excellent summary of recent results in the field of experimental renal hypertension and their application to the pathogenesis and treatment of human hypertension. Goldblatt reviews earlier and at best partially successful attempts at producing hypertension experimentally by various procedures applied to the kidney and then describes his classic work in producing chronic and malignant hypertension in dogs and other species by moderate and severe constriction of the renal arteries. He points out that in long-standing chronic experimental renal hypertension there is little arteriosclerosis and arteriolosclerosis but that the pathologic changes found in experimental malignant hypertension resemble those found in malignant hypertension in man. In discussing the pathogenesis of experimental renal hypertension, Goldblatt considers that a neurogenic mechanism is not involved but that the anterior pituitary and the adrenal cortex may possibly be concerned. He then discusses the renin-hypertensinogen-hypertensin-hypertensinase system and indicates that the origin of renin from the renal tubule cells or the cells of the juxtaglomerular apparatus is still unsettled. He suggests that the alteration in renal circulation produced by renal artery constriction may produce experimental renal hypertension through an increased secretion of renin by the kidney. He considers less likely the possibility that pressor amines or other recently demonstrated vasoactive substances produced by the kidney play significant roles in pathogenesis. Goldblatt reviews the largely negative results with various drugs (including thiocyanate), vitamins, hormones and renal extracts in the treatment of experimental renal hypertension and points out that the results in essential hypertension have not been dissimilar. He favors the view that the therapeutic and prophylactic effects of heterologous hog renin in experimental renal hypertension are due to antirenin and in doing so commits several important errors in presenting the work of Wakerlin and associates in this field. He points out that sympathectomy has no significant effect in reducing the blood pressure of renal hypertensive dogs and suggests that when there is an effect in essential hypertension, a neurogenic factor may be involved pathogenetically. On the basis of results obtained with unilateral nephrectomy in experimental renal hypertension, Goldblatt wisely recommends this procedure for human hypertension only when the renal involvement is definitely unilateral. On the basis of admittedly incomplete evidence, he favors the renal origin of essential hypertension. This monograph is definitely recommended to all students and practitioners of medicine who wish to remain abreast of research in a field which should some day bear the fruit of understanding, successful treatment, and even prevention of human hypertension.

The Frontal Lobes. Proceedings of the Association December 12 and 13, 1947. New York. Editorial Board: John F. Fulton, M.D., Charles D. Aring, M.D., S. Bernard Worts, M.D. Research Publications Association for Research in Nervous and Mental Disease, Volume XXVII. Cloth. Price, \$12.50. Pp. 901, with 237 illustrations. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1948.

The momentous discovery by Egas Moniz, in 1935, that certain mental disorders could be relieved by surgical operations on the frontal lobes has stimulated an enormous amount of work along various lines. The present volume, containing the papers presented at the meeting of the Association for Research in Nervous and Mental Disease, in December 1947, is at once a record of work done and a signpost toward further researches. The first half is devoted to experimental work of various kinds and the second to clinical experiences, particularly with frontal lobotomy. In his preface, Fulton states: "The tenor of the lobotomy papers is of challenging interest, both in respect of the improvement reported in groups such as schizophrenics, and also in the remarkable results in connection with the relief of intractable pain."

The contributions vary greatly in style and cogency. Some are difficult to follow, although the editors are to be commended for their efforts to clarify. Other papers are almost too brief, and reveal tantalizing glimpses of work well begun, but bristling with unanswered questions. Psychological studies and speculative contributions are rather disappointing. Rylander, of Stockholm, has a fine chapter on personality alterations after lobotomy, although one must suspect that in many of his patients the lobotomy was too extensive, and that more restricted lesions would have led to better clinical results. The mystery as to why lobotomy should relieve the intolerable pain of cancer, tabes dorsalis, phantom limb, and so on is not solved, particularly since it appears that the pain threshold and reaction tests are indicative of even greater sensitivity after lobotomy. Another paradox requiring solution is the production of rage by one observer and its abolition by another, both apparently working on the same area in the frontal lobe in animals. In addition to chapters dealing with psychosurgery, there are also discussions of language disorders, epilepsy, motor and autonomic reactions in relation to the frontal lobes. Now, it appears that those areas of the brain, considered by a former generation to be silent areas, are gradually yielding their secrets to those who know what questions to ask and how to interpret the answers.

Pharmacology, Therapeutics and Prescription Writing for Students and Practitioners. By Walter Arthur Bastedo, Ph.G., Ph.M., M.D., Consulting Physician, St. Luke's Hospital, New York. Fifth edition. Cloth. Price, \$8.50. Pp. 840, with 82 illustrations. W. B. Saunders Co., West Washington Sq., Philadelphia 5, 1947.

Bastedo's "Pharmacology, Therapeutics and Prescription Writing" is intended for students and practitioners. This book provides information that is of practical importance in the everyday life of a practitioner and student. There are those who insist that the subject of therapy today has become so broad that it is impossible to include in one volume all of the essential information. If there is adequate reason for this attitude, Bastedo's book is one of several that should be in a medical library. If, however, there are some who feel that only one book is necessary, this volume could be considered as one of several choices. The tenet of the author in his writings is obvious in his introduction, which begins "Medicine sometimes cures, it often relieves, it always consoles." He has discussed with discerning clarity treatment measures that are in common use and the actions of drugs that are well known or should be well known.

Pathologie des Kohlehydratstoffwechsels. Von Prof. Dr. E. Frank, Direktor der II. medizinischen Klinik der Universität Istanbul. Cloth. Price, 24 Swiss francs. Pp. 332, with 20 illustrations. Benno Schwabe, Klosterberg 27, Basal 10; imported by Grune & Stratton, Inc., 381 4th Ave., New York 16, 1949.

While the study of the pathology of carbohydrate metabolism is well presented here, the volume is designed for the investigator and student of internal medicine and the preclinical sciences rather than as a practical guide to the clinician. In the opening section, the researches on experimental diabetes are divided into three periods, the Minkowski-Banting era (pancreatic diabetes and insulin), the Houssay-Young-Long era (the roles of the anterior pituitary gland and the adrenal cortex in carbohydrate metabolism) and the alloxan diabetes era. This is followed by sections on types of pituitary diabetes in human pathology, insulin, pathologic anatomy of the pancreas in diabetes mellitus, diabetic coma, hyperinsulinism, the pathology of the renal threshold, and glycogen disease (Von Gierke's disease). An extensive discussion of acidosis is also included. The presentation concludes with a brief discussion of the so-called benign melliturias. The collection and evaluation of the literature on the pathology of carbohydrate metabolism is extensive and has been done with care: the book should be of great value to the pathologist, the physiologist and the biochemist. An extensive bibliography of some 23 pages covers the literature to the period of 1947. It might be mentioned that a legend of the discovery of pancreatic diabetes by Minkowski in 1889, new to this reviewer, is related in the opening chapter. Since Minkowski was the "great and honored teacher" of Dr. Frank, this should be authentic.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

PERSISTENT LACTATION

To the Editor:—A patient, aged 32, complains of persistent lactation since the birth of her only child seven years ago. This patient is able to express a cubic centimeter or more of milk from either breast at will. The patient did not nurse her baby, but her breasts were pumped several times while in the hospital to relieve engorgement. She has now been divorced three years and denies any sexual stimulation. The patient is a slender, rather nervous person with small, soft, slightly pendulous breasts and erect nipples. Evidences of mastitis or other masses are absent. Pelvic examination reveals a normal uterus and adnexa. Some months ago she was given methyl testosterone in the form of metandren® linguets, 10 mg. daily for two weeks, without any appreciable effect. I have given her four doses of testosterone propionate, 25 mg. by intramuscular injection, without appreciable effect. What treatment will alleviate this condition?

Fred S. Taber, M.D., New Brunswick, N. J.

ANSWER:—The statement, "This patient is able to express a cubic centimeter or more of milk from either breast at will" probably indicates that the patient is doing just that. This is all the stimulation that the breast needs to continue lactating. Have her try leaving the breast absolutely alone and wearing an uplift brassiere. A small pad can be worn under the brassiere to absorb the milk. Lactation probably will stop in two to six months if the breast is not stimulated by manipulation or stripping.

DETERMINATION OF THE SEX OF OFFSPRING

To the Editor:—Explain the fact that in almost all animal life the sex of offspring is the same as the relatively stronger parent, because of either age, state of health or natural physical strength. In the process of development when is sex established?

Johnson Underwood, M.D., Parkville, Mo.

ANSWER:—In the human being, neither age, state of health nor natural physical strength has anything to do with the determination of sex of the offspring. The sex is determined at the time of fertilization of the ovum by the spermatozoon. It is the spermatozoon which determines the sex and not the ovum. All sperm and ova have 48 chromosomes to begin with. Each sperm cell has 46 regular chromosomes plus an "x" and a "y" chromosome, whereas each ovum contains 46 regular chromosomes, plus two "x" sex chromosomes. When maturation occurs each sperm cell and ovum divides into two cells. Each of the two ovum cells contains 23 regular chromosomes plus an "x" chromosome, but one half of the sperm cells contain 23 regular chromosomes plus an "x" chromosome and the other half of the sperm cells contain 23 plus a "y" chromosome. If a sperm cell containing 23 chromosomes plus "x" fertilizes an ovum, a female will result because in the union of the sperm and ovum there will be 46 regular chromosomes plus an "x" and an "x" chromosome. If, on the other hand, a sperm cell containing 24 chromosomes plus a "y" fertilizes an ovum, a male will result because in the union there will be 46 regular chromosomes plus an "x" and a "y" chromosome. It is purely a matter of chance as far as we know at present whether a sperm with an "x" or a "y" chromosome will fertilize an ovum. This is borne out by the fact that almost universally about 94 females are born to every 100 males in single births.

ACUTE NEPHRITIS

To the Editor:—A 21 year old white man has had albumin, casts, red cells and white cells in his urine for the last five months. Ankle edema and decreased renal function are also present. I have diagnosed this as nephritis. How long must I keep him from his work? He has worked little during the past five months, as he has been mostly in bed.

Simon Cherkasky, M.D., Kaukauna, Wis.

ANSWER:—If the patient's nephritis is an initial attack and if there is still evidence of progressive inflammation in the form of urinary changes, decreasing renal function or elevation in blood pressure, it would be inadvisable to allow the patient to return to work. If, however, the renal process has become stabilized, there is little to be gained by further bed rest after a period of five months; gradual increase in activity and ultimate return to light work should be permitted. The work should not involve exposure to chilling or infection, if possible.

DIURETIC ACTION OF ASCORBIC ACID

To the Editor:—A patient with glomerulonephritis had intractable edema until we gave her heavy doses (1 Gm. daily) of vitamin C. What is the explanation.

Bernhard A. Fedde, M.D., Brooklyn.

ANSWER:—W. Evans (*Lancet* 1:308, 1938) reported some diuretic action of ascorbic acid given orally in patients with cardiac failure under control conditions. However, the effect was considerably less than that of ammonium chloride or the purine drugs. Similar results were reported by C. F. Shaffer (J. A. M. A. 124:700, 1944): Intravenous ascorbic acid had no diuretic effect. In 15 out of 20 patients given a mixture of 2 cc. of mercuraphylline and 500 mg. ascorbic acid intravenously, an increased urinary output of 500 cc. to 2,000 cc. over the control period occurred in the first twenty-four hours. D. W. Chapman and C. F. Shaffer (*Arch. Int. Med.* 79:449, 1947) published similar results from the intravenous injection of 2 cc. of meralluride sodium solution and 500 mg. ascorbic acid. The mechanism of this modest diuretic effect is not known, since there have not been studies on urinary sodium excretion. Presumably the effect is on the kidney, but the delayed action after oral administration in the absence of any evidence of acidosis suggests a metabolic effect.

TESTOSTERONE THERAPY

To the Editor:—I have had requests from middle-aged men for injections of testosterone. Will such medication stimulate or cause cancer of the prostate or other organs? What tests can one make to rule out possibility of cancer before injecting testosterone?

M.D., Oklahoma.

ANSWER:—Before starting a male patient on androgenic hormone therapy, it is, of course, imperative that a careful rectal examination of the prostate be performed. Any firm or fixed nodule is suggestive of cancer and contraindicates use of testosterone. A perineal biopsy would be the procedure of choice in confirming the diagnosis. A serum acid phosphatase determination may be of value, and an elevated level is significant of prostatic carcinoma.

One is not likely to find cancer cells in prostatic secretions examined by the ordinary method. Loss of weight, dysuria, back pain and anemia lead to the suspicion of a mitotic process in the prostate of the elderly man.

Testosterone is of value in aiding erections and easing the mental attitude during the male climacteric and is often of value in decreasing nocturia and easing the irritable bladder.

RADIOTHERAPY IN CANCER OF RECTUM

To the Editor:—What value has high voltage roentgen therapy in treatment of carcinoma of the rectum?

M.D., Illinois.

ANSWER:—Radiotherapy is, in general, not as good as radical operation, either as a cure for carcinoma of the rectum or as an attempt to relieve symptoms. Generally, roentgen treatment is used as a palliative procedure and is given in doses of approximately 1,500 to 2,500 r per field. This is usually supplemented, in favorable cases, by interstitial radium in the form of needles or seeds. Preoperative roentgen treatment is seldom used for a strictly operable case, but it may be used in some of the higher grade lesions, strictly those of questionable operability. Recently there have been reports of the use of contact roentgen therapy for lesions low in the bowel which offer promising results.

VASODILATORS IN ACUTE CORONARY DISEASE

To the Editor:—Assuming that vasodilator drugs are contraindicated for acute myocardial infarction, why do some reputable cardiologists employ intravenously administered aminophylline during an attack?

Thomas E. Burrow, M.D., Carlisle, Ark.

ANSWER:—Vasodilator drugs are not used as a rule in acute myocardial infarction because their dilating effect on the peripheral arterioles is such that a considerable fall in blood pressure may develop. Such a fall in blood pressure may affect the coronary flow adversely.

The value of intravenously administered aminophylline during a coronary attack is a controversial question. Even if the drug does increase blood flow to the noninfarcted areas in the heart it is doubtful that blood supply to the infarcted areas is increased enough to make any appreciable difference in the final result. Furthermore, the drug may produce a fall in blood pressure by its dilating action. This may be counterbalanced by an increase in cardiac output, as experiments with aminophylline in congestive heart failure have shown. Thus, the net result of the drug is much in doubt.

DRUG ALLERGY

WILLIAM B. SHERMAN, M.D.
New York

The phenomena of idiosyncrasy to drugs have long presented a problem to physicians, but it is only recently that progress has been made in elucidation of the mechanism of many of these reactions. A considerable number of reactions are due to immunologic hypersensitivity or allergy, unrelated to the drug action. The recognition of allergic manifestations as such is made more difficult by the pharmacologic activity of these agents, and in some cases the distinction between allergic and toxic reactions cannot be made with certainty.

PATHOLOGIC CHANGES

In recent years, numerous studies of the histologic lesions of drug hypersensitivity, as distinguished from toxic effects, have been reported. Arteritis, with localized fibrinoid and hyaline degeneration of the media and perivascular infiltration, has been described in allergy to a number of different drugs.¹ Focal necrosis of the myocardium, liver, spleen and other organs, with infiltration of mononuclear cells, is also characteristic. The monocyctic infiltration may produce granulomas of these organs or, in the heart, extensive interstitial myocarditis.² Figure 1 shows arteritis due to sulfadiazine, and figure 2 shows granuloma of the liver due to sulfadiazine. A similar monocyctic infiltration of the periportal spaces of the liver due to arsphenamine sensitization may be associated with obstruction of the bile canaliculi causing jaundice.³ There is also evidence that massive parenchymal necrosis of the liver due to arsphenamine, cinchophen and sulfonamide drugs may represent a sensitization phenomenon.

SYMPTOMS

The symptoms of drug allergy are varied; some, such as asthma, urticaria, contact dermatitis and anaphylactic shock, are readily recognized as allergic manifestations, while others, such as fever, leukocytosis, arthralgia and morbilliform and scarlatiniform rashes, are easily confused with the symptoms of infectious diseases.

The most dramatic of allergic manifestations, anaphylactic shock, is familiar as a reaction to the injection

of heterologous antiserum into sensitive patients. Similar reactions (occasionally fatal) may be produced by injections of other protein-containing biologic products, such as liver extract, insulin, toxoids and vaccines, and occasionally by the intravenous injection of such non-protein drugs as arsphenamine, quinine and thiamine. These reactions may occur unexpectedly, but often mild evidences of sensitivity will follow one or two injections before the occurrence of a severe anaphylactic reaction; these should suggest caution in administering further injections.

Asthma and rhinitis due to drug allergy are not unusual, most often affecting persons who also have the same symptoms from other causes. The drug most frequently causing these symptoms is aspirin (acetylsalicylic acid), but sulfonamide drugs, penicillin, quinine, arsphenamine, vegetable gums and protein drugs, such as pancreatin and papain, are occasional causative agents. Attacks of asthma caused by acetylsalicylic acid usually start within a few minutes, because of its solubility and diffusibility, so that the relationship of cause and effect is apparent. The severity of the attacks is such that in several cases death has resulted from ingestion of 5 to 10 grains (0.3 to 0.6 Gm.). Cutaneous tests are not helpful in such sensitivity to crystalloid drugs. In the case of asthma and rhinitis due to vegetable gums and proteins, scratch or intracutaneous tests are diagnostic. Sensitizations to the vegetable gums are of practical importance because of the use of gums as excipients or cohesive agents in the preparation of pills. Most pills contain one of the gums, the presence of which is usually disregarded, and the possibility must be considered that a reaction following their use may be due to allergy to the gum rather than the pharmacologically active ingredient.⁴

Drugs of practically all types, crystalloids, proteins and gums, may cause urticaria and angioedema. In recent years the drug most frequently causing urticaria has been penicillin. Urticaria due to penicillin may occur as the sole manifestation of sensitization or may form a part of a syndrome resembling serum sickness in every respect, with urticaria, fever and arthralgia. The reaction is usually delayed seven to ten days after the first dose and frequently two or three days after use of the drug is discontinued. If the penicillin has been injected in oil and wax, the general features of the reaction are similar, but, in addition, there is usually a pronounced swelling at the site of injection, due to persistence of antigen at that location.

Fever due to drugs is an important and confusing manifestation of drug allergy, most frequently seen after administration of sulfonamide drugs, but also caused by

penicillin, streptomycin, thiouracil, iodides and other drugs. During the first course of any of these drugs, fever usually appears abruptly on the seventh to tenth day. The temperature may rise to 105 or 106 F., and the leukocyte count may remain normal or rise as high as 30,000. The fever is frequently, but not always,

Fig. 1.—Arteritis following use of sulfathiazole (from Dr. Arnold Rich).

accompanied with morbilliform or scarlatiniform rash and may be easily mistaken for one of the acute infectious diseases. In cases in which the sulfonamide drugs have been used for pneumonia or pyogenic infection, the sudden rise of temperature, if accompanied with leukocytosis and not a rash, suggests a spread of infection. Such a misinterpretation may lead the physician to continue or increase the dose of the sulfonamide drug and occasionally has resulted in death from sensitivity due to drugs.⁵ The diagnosis of drug fever is rarely easy, but if one keeps in mind the possibility of its occurrence, the characteristic incubation period of seven to ten days and the rash and leukocytosis which may or may not accompany it, it may be suspected and a suitable substitute made for the previous medication.

When use of the causative drug is discontinued, the fever subsides in two or three days. The patient remains sensitive for a considerable period, and a single subsequent dose may cause an abrupt rise of temperature within a few hours. The administration of sulfonamide drugs for two to five days may initiate the process of sensitization, though the drug may be eliminated from the body before fever develops. Subsequent administration of the same drug will then cause an immediate reaction.

In the case of drugs injected once or twice a week, such as arsphenamine and oxophenarsine hydrochloride, drug fever occurs abruptly after the second or third injection, producing the picture of Milian's "syndrome of the ninth day."⁶

Drug fever is rarely serious if recognized as such and use of the causative agent discontinued, but it is an indication that sensitization has taken place and further use of the same or closely related drugs may give rise to more serious manifestations of drug allergy.

Rashes due to drugs are the commonest manifestations of drug allergy. Their morphologic appearances are exceedingly varied, some forms being characteristic of certain types of drugs, as the acneform dermatitis produced by bromides and iodides, while others, such as the morbilliform rashes following internal medications and vesicular contact dermatitis, may be due to a wide variety of agents.

When the drug, such as one of the sulfonamide drugs, is given in a continuous course, the morbilliform rash most often appears on the seventh to fourteenth day, often accompanied with drug fever. If use of the drug is stopped, the rash fades promptly, but if it is con-

Fig. 2.—Granuloma of the liver following use of sulfadiazine.

tinued the eruption usually becomes more intense and may progress to an exfoliative dermatitis which is exceedingly persistent even after administration of the drug has been discontinued. Once the skin has been sensitized, subsequent use of the drug may cause a

prompt appearance of an intense confluent eruption and topical application of the drug may cause vesicular contact dermatitis.

Sensitization of the skin may also be initiated by topical application, continued local use of such drugs as the sulfonamide preparations for two weeks or more frequently causing contact dermatitis.⁷ If the same drug is subsequently administered by mouth there is usually a prompt recurrence of dermatitis at the sites of previous contact. In a considerable number of patients this local recurrence is accompanied with constitutional symptoms, such as chills, fever and eosinophilia,⁷ indicating that surface contact has produced a systemic rather than merely a cutaneous sensitization.

Jaundice may occur after the administration of a wide variety of drugs. In certain instances, as with chloroform and carbon tetrachloride, there is little doubt that damage to the liver is a normal toxic effect of the drug. In the case of other drugs, such as sulfonamide preparations, arsphenamine, cinchophen and quinacrine hydrochloride, there is reason to believe that jaundice occurs as a result of sensitization. Hanger and Gutman⁸ pointed out that jaundice occurring early in the course of arsphenamine treatment and showing the blood chemical observations of obstructive jaundice is presumably due to drug sensitivity. It is probable that drug sensitivity can also cause nonobstructive jaundice, but series of cases of postarsphenamine jaundice to which these chemical criteria have not been applied undoubtedly include cases of coincidental infectious hepatitis and of homologous serum jaundice transferred by the technic of injecting the drug, so that results based on them must be interpreted with caution.

All of the drugs causing jaundice are also common causes of other manifestations of allergy, such as drug fever and cutaneous rashes, and not infrequently jaundice occurs with or follows soon after one of these evidences of sensitization. When a drug is given in an interrupted course, jaundice is more frequent in the second course, suggesting that sensitivity has been acquired. After one attack of jaundice, further use of the same drug is apt to cause a recurrence.

Another type of dangerous reaction to drugs which has been suspected of having an allergic mechanism is granulocytopenia caused by such drugs as aminopyrine, thiouracil, arsphenamine and the sulfonamide preparations. Agranulocytosis may occur suddenly in patients who have previously tolerated the same drug for weeks or months, or after a gradually developing leukopenia. If recovery occurs, a subsequent dose of the causative drug may produce a decided drop in the leukocyte count within a few hours. Dameshek and Colmes⁹ reported positive cutaneous reactions to a mixture of aminopyrine and human serum in 3 patients suffering from agranulocytosis due to that drug. These observations are suggestive of an allergic mechanism, but have not yet received adequate confirmation.

Granulocytopenia due to drugs is occasionally accompanied with thrombopenia, which may also occur as a separate reaction to the sulfonamide drugs, arsphenamine and to other drugs, but most often to the hypnotic

sedormid[®] (allyl-isopropyl-acetyl-carbamide). Thrombopenia caused by drugs is usually manifested by purpura appearing abruptly after prolonged use of the drug. After one such attack, further administration of the same drug usually causes a prompt recurrence.

DIAGNOSIS AND MANAGEMENT

Most forms of allergy to protein drugs are readily demonstrable by scratch or intracutaneous tests with the causative agent. In allergy to nonprotein crystalloid drugs, such tests are rarely helpful. Since the antigenic activity of crystalloid drugs is believed to result from combination with proteins within the body, a few workers have used drug azoproteins as antigens for cutaneous tests, but the results reported have been disappointing. Leftwich⁹ reported success in the use of serum of patients receiving full doses of sulfonamide drugs as antigens in intracutaneous tests for the diagnosis of sensitivity to sulfonamide drugs. No confirmation of this work has been published, and Fink, Burton and Wheeler¹⁰ reported negative results from the use of this method in children. The writer has performed this test on patients known to be highly sensitive to sulfadiazine, with uniformly negative results. It is not a reliable criterion of sensitization to sulfonamide drugs. The only type of cutaneous test with nonprotein drugs which has proved of diagnostic value is the patch test in contact dermatitis. Frequently the patch test is also helpful in the diagnosis of dermatitis resulting from internal medication, but it is less reliable in such cases, because of the uncertainty of absorption of drugs through the intact skin.

In general the diagnosis of drug allergy depends on a knowledge of the clinical manifestations of sensitivity which may be expected from each drug used. The history of a hereditary tendency to allergic disease is of little aid in diagnosis except of those reactions manifested by asthma, rhinitis and urticaria. Many of the more serious types of drug allergy may be avoided if minor symptoms of sensitization, such as cutaneous rashes and fevers due to drugs, are recognized as such and use of the causative drug is promptly discontinued.

The specificity of drug allergies varies so greatly that it is impossible to predict the results of substitution of a closely related drug for one which has produced a reaction. Some patients react to a whole group of chemically related compounds, while others show a sensitivity specific for one drug of the group. Only a cautious trial with a fraction of the usual dose will give the answer in an individual case.

Likewise, the duration of drug sensitization is exceedingly variable, in some instances lasting for years and in others, especially in sensitization to penicillin, ending within a few weeks. If an acceptable substitute is available, the wisest procedure is to avoid readministration of a drug which has once caused an allergic reaction for an indefinite period. Occasionally strong indications for the use of an important drug may outweigh the history of allergic reactions to previous administration, and cautious trial, starting with a fractional dose, is warranted. In the case of penicillin,

such attempts are often successful; with the sulfonamide drugs, the results are less favorable.

While desensitization is often possible with protein compounds, attempts at desensitization with nonprotein drugs are rarely successful and occasionally cause severe reactions. In general substitution of another medication is preferable.

SUMMARY

Many of the untoward reactions to drugs, such as anaphylactic shock, asthma, rhinitis, urticaria, arthralgia, drug fever, dermatitis and probably hepatitis, granulocytopenia and thrombopenia, are due to allergic sensitization. Pathologic studies have demonstrated widespread visceral lesions in patients with clinical evidence of drug allergy. Scratch and intracutaneous tests with nonprotein drugs are rarely diagnostic. Patch tests are of value in contact dermatitis and occasionally in other eruptions due to drugs. The diagnosis of drug allergy in most cases must depend on the history and physical manifestations. Recognition of early signs of sensitization and discontinuation of use of the causative drug will often avoid the more serious types of reaction.

ABSTRACT OF DISCUSSION

DR. MARION B. SULZBERGER, New York: Rashes are the commonest manifestations of drug allergies. It is therefore not astonishing that the older dermatologic literature is where one must look to get the historical background of this important chapter of medicine. In 1877 Dr. Prince Morrow of New York published one of the best treatises on rashes and eruptions due to drugs. In 1893 Josef Jadassohn published a monograph entitled "Medicamentous Dermatitis," an almost prophetic treatise in which almost everything we know today is discussed. Simple chemicals of relatively low molecular weight, chemicals which can be synthesized in the laboratory, even elements such as mercury, can induce almost every known form of immunologic change. As a result, in studying the basic phenomena of immunology, one need not employ as antigens the impure mixtures and complex inconstant combinations derived from nature. The second important point is that almost every known disease picture can be caused by the immunologic reactions to such simple chemicals. In other words, there is nothing pathognomonic for disease produced by a living micro-organism, as distinguished from disease elicited by simple nonliving chemical substances. Thus, identical forms of arthritis, urticaria, asthma, erythematous eruptions, rhinitis and fever can be caused by infecting living agents, by "protein" allergens and also by salicylates and many simple chemicals. Hepatitis can be due to a virus, on one hand, to a drug allergy, on the other hand, to direct toxic action, such as that of chloroform, or to combinations of these. One of the most illuminating prospects in all medicine is offered by the study of the reasons for these frequent similarities of the disease pictures caused by living agents and by nonliving chemicals. Dermatologists' combined studies of cutaneous diseases and cutaneous reactions due to simple chemicals and drugs and the diseases and cutaneous reactions due to living micro-organisms have made clearer one great fact. Many important micro-organisms, such as tubercle bacilli, lepra bacilli, spirochetes and dermatophytic fungi, produce disease not by forming toxins, but by producing allergens which specifically sensitize the tissues. The picture the physician sees is mainly the result of the immunologic reaction of the sensitized tissue to the products of the micro-organisms. With this concept in mind, one can begin to comprehend the similarities of the disease pictures produced by certain living agents and those produced by simple chemical allergens. Both

are based on analogous immunologic alterations, and, more important, both can and must be studied by related and integrated theoretical concepts and experimental approaches.

DR. HOWARD OSGOOD, Buffalo: While Dr. Sherman considered a number of drugs, I should like to add one more. This is papain, derived from the fruit of the papaya tree or East Indian paw paw. The omission is undoubtedly due to the fact that sensitivity to it is not the usual so-called drug sensitivity, but is of the atopic type. Papain is a powerful protein digestant and occurs as a powdered extract in many proprietary and other digestant mixtures sold in drug stores. Papaya is used as a meat tenderizer in hamburger and other ground meats, being introduced shortly before cooking. It is used in treating hides. It is used extensively as a clarifier in beer and ale, although the amount present is in large dilution. The juice is canned and sold for drinking. In persons sensitive to it, exposure produces vasomotor rhinitis and asthma, which may be severe, and digestive symptoms.

DR. THEODORE LOUIS SQUIER, Milwaukee: It would be most most helpful if determinations of aminopyrine sensitivity or of sensitivities to other drugs were possible by a cutaneous test such as that described by Dameshek and Colmes, or by some modification thereof, such as was described by Leftwich. My co-workers and I have used the cutaneous test procedure advocated by Dameshek and Colmes, i. e., mixing of aminopyrine with human serum and later testing patients intracutaneously with the drug-serum mixture, with consistently negative results. Likewise, in a fairly extensive series of patients known to be sensitive to sulfonamide drugs, we have made cutaneous tests as described by Leftwich, using blood serum with a high content of a sulfonamide drug from patients treated with sulfonamide preparations. The results were uniformly negative. It is important to emphasize that when cutaneous tests are done with any serum, one may be confused by false positive reactions due to isoantibodies in the serum. Any one who has done passive transfer tests will recall how frequently the reactions are observed to the serum used in sensitizing the skin sites.

DR. J. A. RUDOLPH, Miami Beach, Fla.: I have under observation a group of patients who have been sensitized by the sulfonamide drugs, penicillin and some of the antihistaminics. I have not been able to determine whether these sensitizations have remained latent or not, since the patients meet none of the usual criteria for an allergic person. Could this not be the reason why one sees more allergic persons today who have asthma, rhinitis or other allergies which may have been initiated by the various drugs in question? It would seem that the immunologic concept of allergy may also be one of precipitation by drugs and need not be dependent on heredity and the other allergic criteria, alone, as we believe at present.

DR. W. B. SHERMAN, New York: I agree with essentially all the points brought out, and particularly Dr. Squier's remarks that no form of cutaneous test is reliable in the diagnosis of sensitivity to drugs. The diagnosis must be made from the knowledge of the particular reaction to be expected from each drug. I would like to stress, also, that some of the apparently minor reactions, such as cutaneous rashes and drug fever, may be warnings that more serious manifestations will take place if use of the drug is continued.

Mrs. John Hunter.—It was about this time that Hunter, at the age of 43, married Anne Home, the daughter of an Army doctor, and 29 years of age. She was a woman of great charm and considerable social distinction, the friend of Haydn, Madame d'Arbly and Mrs. Montague. She was something of a poetess and wrote the words for Haydn's "The Creation."—Souttar, H.S., The Hunterian Oration, *Annals of the Royal College of Surgeons of England*, March 1949, page 127.

PATHOGENESIS OF ARTERIAL HYPERTENSION

IRVINE H. PAGE, M.D.
Cleveland

Much is known of the pathogenesis of spontaneous hypertension in human beings and experimental hypertension in animals, despite the short time during which modern investigative methods have been used. Because the various types of experimental renal hypertension have received the greatest share of study is insufficient reason for one's assuming that they necessarily mirror more exactly essential hypertension in human beings. Several years ago, some clinicians overstepped judicious bounds in proclaiming that the cause of human hypertension had been reproduced in animals, a view wisely not expressed at that time by the inspirer of some of this work, Harry Goldblatt. But there are certainly enough similarities between experimental renal hypertension and essential hypertension to justify the hope that elucidation of the mechanism of the former will aid in the understanding of the latter.

For some years, the view was held that hypertension was due to humoral agents. A poor case at best was made for any participation of the nervous system. Indeed, at one time, the nervous system was discarded almost contemptuously; but times have changed. The nervous system now occupies the dominant place, in the opinion of many persons, in maintaining the elevated pressure during the chronic stage. Humoral agents merely initiate the rise during the first few weeks of hypertension, to lose their dominance later. But confusion becomes compounded. Because renin has not been detected with assurance in peripheral blood in increased amounts during the chronic stage of hypertension by the crude methods available, it is assumed that it plays no part in the mechanism. The assumption is made further, on the basis of what seems to me assailable evidence, that the nervous system now takes over the vasoconstrictor function from the humoral. Confronted with this array of inadequate evidence, some resign themselves to the belief that doctors are wholly lacking in insight into the mechanisms of arterial hypertension.

Even the simplest hypertension is a mosaic in which many mechanisms are to a greater or lesser extent involved. Elevated blood pressure is the resultant of multiple forces acting on the variety of tissues which compose the circulatory apparatus. Is it then to be supposed that this is any simple problem the solution of which will be found in the elucidation of but one of these forces?

The various systems chiefly involved in hypertension may be divided, for pedagogic purposes, into groups somewhat as follows:

Clinical

Experimental

I. NERVOUS PARTICIPATION

Poliomyelitis of brain stem	Cerebral Ischemia
Porphyria	
Increased intracranial pressure	Cushing's experiment
Sclerosis of carotid sinus	Resection of sinus and aortic depressor nerves

From the Research Division of the Cleveland Clinic Foundation and Bunts Institute, Cleveland.

Read in a Symposium on Hypertension in a joint meeting of the Section on Experimental Medicine and the Section on Internal Medicine at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 25, 1948.

Clinical

Experimental

Resection of glossopharyngeal nerve
Emotion
Tabes dorsalis

Hypertension from audiogenic stimulus

II. CARDIOVASCULAR PARTICIPATION

Coarctation of aorta
Heart failure
Arteriovenous fistula
Arteriosclerosis

Clamping of aorta above renal vessels

III. ENDOCRINE PARTICIPATION

Hypophysis—basophil adenoma
Adrenals—pheochromocytoma
Cortical carcinoma
Cortical hyperplasia
Thymus—carcinoma with Cushing's syndrome
Placenta—associated with toxemia of pregnancy

Anterior lobectomy diminishing blood pressure

Adrenalin hypertension
Desoxycorticosterone acetate hypertension
Bilateral adrenalectomy abolishes hypertension

IV. RENAL PARTICIPATION

Glomerulonephritis
Obstruction to renal vessels
Pylonephritis
Prostatic obstruction
Polycystic kidneys
Crush syndrome
Periarteritis nodosa
Perinephric constriction of the parenchyma

Antikidney serum nephritis
Mechanical constriction of renal arteries or veins

Mechanical compression of ureters

Cellophane or silk perinephritis

NEUROGENIC HYPERTENSION

Persistent hypertension of neurogenic origin has been induced in animals by section of the carotid sinus and aortic depressor nerves and by cerebral ischemia resulting from ligation of the blood supply to the brain. Neither method produces hypertension which exactly simulates essential hypertension in human beings; nor could it currently be supposed that the mechanism of the neurogenic component of this disease is faithfully mirrored in these experimentally induced hypertensions. Yet the fact that blood pressure can be persistently elevated by experimental alteration of the nervous system gives hope that the way in which it actually participates may be elucidated.

Koch and Mies¹ were the first to show that sustained hypertension resulted when the carotid sinus and aortic depressor nerves were severed. Subsequent work, chiefly by Heymans,² Grimson,³ Thomas⁴ and Bing⁵ shows that the hypertension is widely fluctuant, depending on concurrent changes in heart rate. The mechanism of the rise in pressure seems to be a disproportion between the volume content of the arterial tree and its capacity. The disproportion is the result of increased cardiac output due to tachycardia exceeding the peripheral blood flow.

Hypertension due to ligation of cerebral arterial flow of an intermittent sort was produced in dogs by

My co-workers and I have used the cutaneous test procedure advocated by Dameshek and Colmes, i. e., mixing of aminopyrine with human serum and later testing patients intracutaneously with the drug-serum mixture, with consistently negative results. Likewise, in a fairly extensive series of patients known to be sensitive to sulfonamide drugs, we have made cutaneous tests as described by Leftwich, using blood serum with a high content of a sulfonamide drug from patients treated with sulfonamide preparations. The results were uniformly negative. It is important to emphasize that when cutaneous tests are done with any serum, one may be confused by false positive reactions due to isoantibodies in the serum. Any one who has done passive transfer tests will recall how frequently the reactions are observed to the serum used in sensitizing the skin sites.

DR. J. A. RUDOLPH, Miami Beach, Fla.: I have under observation a group of patients who have been sensitized by the sulfonamide drugs, penicillin and some of the antihistaminics. I have not been able to determine whether these sensitizations have remained latent or not, since the patients meet none of the usual criteria for an allergic person. Could this not be the reason why one sees more allergic persons today who have asthma, rhinitis or other allergies which may have been initiated by the various drugs in question? It would seem that the immunologic concept of allergy may also be one of precipitation by drugs and need not be dependent on heredity and the other allergic criteria, alone, as we believe at present.

DR. W. B. SHERMAN, New York: I agree with essentially all the points brought out, and particularly Dr. Squier's remarks that no form of cutaneous test is reliable in the diagnosis of sensitivity to drugs. The diagnosis must be made from the knowledge of the particular reaction to be expected from each drug. I would like to stress, also, that some of the apparently minor reactions, such as cutaneous rashes and drug fever, may be warnings that more serious manifestations will take place if use of the drug is continued.

Mrs. John Hunter.—It was about this time that Hunter, at the age of 43, married Anne Home, the daughter of an Army doctor, and 29 years of age. She was a woman of great charm and considerable social distinction, the friend of Haydn, Madame d'Arblay and Mrs. Montague. She was something of a poetess and wrote the words for Haydn's "The Creation."—Souttar, H.S., *The Hunterian Oration, Annals of the Royal College of Surgeons of England*, March 1949, page 127.

PATHOGENESIS OF ARTERIAL HYPERTENSION

IRVINE H. PAGE, M.D.
Cleveland

Much is known of the pathogenesis of spontaneous hypertension in human beings and experimental hypertension in animals, despite the short time during which modern investigative methods have been used. Because the various types of experimental renal hypertension have received the greatest share of study is insufficient reason for one's assuming that they necessarily mirror more exactly essential hypertension in human beings. Several years ago, some clinicians overstepped judicious bounds in proclaiming that the cause of human hypertension had been reproduced in animals, a view wisely not expressed at that time by the inspirer of some of this work, Harry Goldblatt. But there are certainly enough similarities between experimental renal hypertension and essential hypertension to justify the hope that elucidation of the mechanism of the former will aid in the understanding of the latter.

For some years, the view was held that hypertension was due to humoral agents. A poor case at best was made for any participation of the nervous system. Indeed, at one time, the nervous system was discarded almost contemptuously; but times have changed. The nervous system now occupies the dominant place, in the opinion of many persons, in maintaining the elevated pressure during the chronic stage. Humoral agents merely initiate the rise during the first few weeks of hypertension, to lose their dominance later. But confusion becomes compounded. Because renin has not been detected with assurance in peripheral blood in increased amounts during the chronic stage of hypertension by the crude methods available, it is assumed that it plays no part in the mechanism. The assumption is made further, on the basis of what seems to me assailable evidence, that the nervous system now takes over the vasoconstrictor function from the humoral. Confronted with this array of inadequate evidence, some resign themselves to the belief that doctors are wholly lacking in insight into the mechanisms of arterial hypertension.

Even the simplest hypertension is a mosaic in which many mechanisms are to a greater or lesser extent involved. Elevated blood pressure is the resultant of multiple forces acting on the variety of tissues which compose the circulatory apparatus. Is it then to be supposed that this is any simple problem the solution of which will be found in the elucidation of but one of these forces?

The various systems chiefly involved in hypertension may be divided, for pedagogic purposes, into groups somewhat as follows:

Clinical	Experimental
I. NERVOUS PARTICIPATION	
Poliomyelitis of brain stem	Cerebral Ischemia
Porphyria	
Increased intracranial pressure	Cushing's experiment
Sclerosis of carotid sinus	Resection of sinus and aortic depressor nerves

From the Research Division of the Cleveland Clinic Foundation and Buuts Institute, Cleveland.
Read in a Symposium on Hypertension in a joint meeting of the Section on Experimental Medicine and the Section on Internal Medicine at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 25, 1948.

Clinical	Experimental
Resection of glossopharyngeal nerve	
Emotion	Hypertension from audiogenic stimulus
Tabes dorsalis	

II. CARDIOVASCULAR PARTICIPATION	
Coarctation of aorta	Clamping of aorta above renal vessels
Heart failure	
Arteriovenous fistula	
Arteriosclerosis	

III. ENDOCRINE PARTICIPATION	
Hypophysis—basophil adenoma	Anterior lobectomy diminishing blood pressure
Adrenals—pheochromocytoma	Adrenalin hypertension
Cortical carcinoma	Desoxycorticosterone acetate hypertension
Cortical hyperplasia	
Thymus—carcinoma with Cushing's syndrome	Bilateral adrenalectomy abolishes hypertension
Placenta—associated with toxemia of pregnancy	

IV. RENAL PARTICIPATION	
Glomerulonephritis	Antikidney serum nephritis
Obstruction to renal vessels	Mechanical constriction of renal arteries or veins
Pyelonephritis	
Prostatic obstruction	
Polycystic kidneys	Mechanical compression of ureters
Crush syndrome	
Periarteritis nodosa	
Perinephric constriction of the parenchyma	Cellophane or silk perinephritis

NEUROGENIC HYPERTENSION

Persistent hypertension of neurogenic origin has been induced in animals by section of the carotid sinus and aortic depressor nerves and by cerebral ischemia resulting from ligation of the blood supply to the brain. Neither method produces hypertension which exactly simulates essential hypertension in human beings; nor could it currently be supposed that the mechanism of the neurogenic component of this disease is faithfully mirrored in these experimentally induced hypertensions. Yet the fact that blood pressure can be persistently elevated by experimental alteration of the nervous system gives hope that the way in which it actually participates may be elucidated.

Koch and Mies¹ were the first to show that sustained hypertension resulted when the carotid sinus and aortic depressor nerves were severed. Subsequent work, chiefly by Heymans,² Grimson,³ Thomas⁴ and Bing⁵ shows that the hypertension is widely fluctuant, depending on concurrent changes in heart rate. The mechanism of the rise in pressure seems to be a disproportion between the volume content of the arterial tree and its capacity. The disproportion is the result of increased cardiac output due to tachycardia exceeding the peripheral blood flow.

Hypertension due to ligation of cerebral arterial flow of an intermittent sort was produced in dogs by

Nowak and Walker⁶ and later by Fishback, Dutra and MacCamy.⁷ However, it was so unpredictable and did not occur at all in so many animals, even after severe ischemia, that many observers doubted its existence. Taylor and I repeated this work and found, as had our predecessors, that ligation of the carotid, vertebral

Fig. 1.—The effect on arterial pressure of progressive ligation of vessels to the dog's head. Changes in pressure are irregular despite severe cerebral ischemia. Dog 280 is represented by the heavy line, dog 348 by the light line and dog 424 by the broken line. The horizontal row of figures at the bottom shows the number of days, and the vertical column of figures at the left shows the blood pressure in millimeters of mercury.

and spinal arteries elicited altogether unimpressive elevations of blood pressure (fig. 1).

We then made a further series of experiments in which all the vessels that could be found going to the head were ligated. These animals usually experienced periodic convulsions and appeared demented, but the elevation in arterial pressure was at least perceptible and often persistent for weeks.

Fig. 2.—The effect of progressive ligation of vessels to the head with daily stimulation by diathermy of a tantalum wire placed just above the obex. Arterial pressure is higher and persists at higher levels for weeks or months. The horizontal row of figures at the bottom shows the time in weeks, and the vertical column of figures shows the blood pressure in millimeters of mercury.

Greater elevation was obtained by implantation of a tantalum wire in the groove of the medulla just above the obex, the exact area being determined by rise in blood pressure at operation following diathermy heat-

ing of the wire. The area of the medulla was subjected to daily fifteen minute treatments with inductothermy. Figure 2 shows the more persistent elevation in blood pressure. Discontinuance of treatment was followed by fall in blood pressure to normal or only slightly elevated levels. The injection of kaolin into the ventricular system of the brain was at one time used as a method of producing neurogenic hypertension. Recently, it has been seriously questioned whether anything but brief elevation in blood pressure may be so produced. Our own experience coincides with this. In dogs we have never produced persistent diastolic hypertension by injection of a variety of specimens of kaolin into the cisterna magna. The problem needs further study.

Fig. 3.—Augmentation of angiotonin (144). 1. Angiotonin. 2-3. Tetraethylammonium chloride, 5 mg. per kilogram of body weight. 4. Angiotonin. 5-8. Tetraethylammonium chloride. 9. Angiotonin. This is an example of augmentation that might have significance in the renal hypertensive state.

An interesting method for the production of hypertension in rats tested for their high emotional responsiveness has been developed by Farris, Yeakel and Medoff.⁸ In these rats, exposed to the sound of an air blast a minimum of 167 times daily, arterial pressures of from 160 to 180 mm. of mercury developed.

In human beings hypertension often follows bulbar poliomyelitis, chronic porphyria, tabes dorsalis and sclerosis of the carotid sinus. It is strikingly evident in the "hypertensive diencephalic syndrome," along with other evidences of diencephalic hyperactivity. Increased intracranial pressure elevates arterial pressure but not persistently. Disturbance of the psyche is believed by many of the psychiatrically minded to be at the bottom of much hypertension. Probably so, but one must await the proof. Thus, there is much suggestive evidence of nervous system involvement in hypertension, but so far it is lacking in the necessary clarity to be of decisive importance in the objective analysis of the problem in patients.

ENDOCRINE PRODUCTION

Selye⁹ and his associates have made an important contribution to inquiry into experimental hypertension. They demonstrated that desoxycorticosterone acetate (D.C.A.) when given to unilaterally nephrectomized female rats, mice or chicks receiving salt in their drinking water, caused severe nephrosclerosis, moderate hypertension and associated vascular changes reminiscent of periarteritis nodosa and rheumatic fever in about three weeks. Monkeys and dogs, even after sixty days of treatment, show only minimal changes. An emulsion of anterior pituitary gland also produces much the same result, presumably because of its stimulating action on the adrenal cortex. But the pituitary and desoxycorticosterone acetate have points of difference, the chief of which being that the action of desoxycorticosterone acetate is unaffected by the protein content of diet, while a 30 per cent casein diet fed after pituitary injection yields 88 per cent of nephrosclerosis as contrasted with 11 per cent on a 15 per cent casein diet. It is possible that the difference in desoxycorticosterone acetate and pituitary action is one of protein metabolism, the former having little or no effect and the latter a profound one. Both desoxycorticosterone acetate and pituitary actions are augmented by sodium chloride. Casein, egg albumin and wheat gluten favor nephrosclerosis, while lactalbumin, gelatin and zein are less effective. Amino acids were ineffective, suggesting that the structural arrangement of a product of protein digestion determines its participation in nephrosclerotic action.

It is not as yet clear why other investigators have not had the same consistent success in reproducing these experiments. All those who have seen the vascular lesions in Selye's rats do not doubt their reality.

In the past years it has become apparent that rare cases of essential hypertension, or what passes for it, seem to originate in a medullary pheochromocytoma. The signs and symptoms of paroxysmal hypertension are not present, and the clinical pattern is that of essential hypertension. The mechanism is obscure, since no one has so far elicited persistent hypertension in animals with epinephrine. Vogt has biologic¹⁰ and Corcoran and I¹¹ chemical evidence that epinephrine stimulates increased liberation of corticoids. Possibly such a mechanism leads to the production of persistent hypertension in patients with a pheochromocytoma.

The production of hypertension by steroids has its striking clinical counterpart. The hypertension of Cushing's disease or syndrome leaves the physician in little doubt that the adrenal cortex is capable of playing a genetic role in its production.

Of the ovary, little need be said, if only because little is known. The far more direct association of the placenta with pregnancy and the toxemias of pregnancy assumes importance in analysis of the production of hypertension. The time-sanctioned "menopausal hypertension" has not withstood critical experimental analysis. It is with regret my co-workers and I record that it does not exist.¹² There can be little doubt that the endocrine system plays a crucial part in the mechanism of hypertension, but just how it does so is not clear.

CARDIOVASCULAR PRODUCTION

It is by no means certain that there is a special type of diastolic hypertension resulting alone from increased force of the heart beat and/or increased cardiac output. The hypertension of hyperthyroidism is systolic, because of increased cardiac output, and thus does not resemble essential hypertension. Possibly the nearest approach is the hypertension of coarctation of the aorta. If Steele's¹³ observation is widely verified, that relative diastolic hypertension exists below the stenosed area as well as above it, it is probable that widespread increase in peripheral resistance has occurred, mediated by nervous or humoral mechanisms or both. The evidence on these points is conflicting and requires more detailed examination before the mechanism will be clear.

My own work merely shows that the aorta of dogs may be clamped off at or near the aortic isthmus without producing significant hypertension proximal to the obstruction.¹⁴ The failure to produce it seems due to the fact that dogs have a remarkable ability to produce collateral circulation. Except for transient weakness in the hind quarters, the animal's blood supply seemed almost unaffected by so drastic a procedure as closing the aorta high in the chest.

RENAL PRODUCTION

A variety of attempts have been made over a period of many years to produce persistent hypertension by operative procedures on the kidneys. These have been associated with the names of such pioneers as Cash, Hartwich, Pässler and Janeway. The results were never wholly satisfying. Probably the best of the methods growing out of this exploration consisted either of reducing the mass of kidney substance by resection of portions of the parenchyma, by ligation of large branches of the main renal artery or by roentgen irradiation of the kidneys transplanted to a position under the skin. These methods had the disadvantage of reducing total renal excretory function, differing thus fundamentally from early essential hypertension in human beings. Goldblatt overcame this disadvantage by the application of constricting clamps on the main renal vessels and so achieved persistent diastolic hypertension without disturbance of renal excretory function. The method has received wide acceptance and has contributed greatly to furtherance of knowledge of experimental hypertension.

The application of cellophane or silk to the parenchyma of the kidneys offers another simple method of producing experimental hypertension. These materials cause irritation with the accumulation of fluid and the ingrowth of fibroblasts. Condensation occurs with the formation of a thick hull around the parenchyma, thus preventing the normal pulsating of the kidneys. Arterial pressure rises slowly over a period of weeks to months without excretory insufficiency.

One other method has been suggested (Dick¹⁵). Streptococci were injected into the blood stream. The method has not as yet been evaluated by other investigators.

Selye¹⁶ produced hypertension by placing a ligature around the aorta at a level between the two renal arteries sufficiently tightly drawn to reduce the pressure below it to a level at which, although blood flow continues, glomerular filtration can no longer occur. Life is maintained by the renal tissue above the tie. Extensive vascular damage occurs, killing the animal within weeks or months. The normal morphologic pattern of the kidney is replaced by aggregates of large cells apparently arising from the epithelium of the lower third of the proximal tubule. The tissue resembles that of adrenal cortex. Selye stated the belief that these cells are the source of renin.

A disturbing note has crept into current theory recently. The position has been vigorously maintained by Goldblatt and Houssay for some years that removal of both kidneys was not associated with rise in blood pressure, despite the observation of Jeffers, Lindauer, Twaddle and Wolferth¹⁷ and Grollman and Rule¹⁸ that the removal of three of the four kidneys in parabiotic rats resulted in hypertension in the nephrectomized animal. In 1947 Braun-Menendez and v. Euler¹⁹ reported that a rise of pressure occurred in only 3 of 23 such pairs. They then joined 3 rats in parabiosis, one bilaterally nephrectomized animal between 2 normal animals. Definite hypertension occurred in all 6 trios. Further, they found that one third of nephrectomized rats showed hypertension usually during the second or third day after nephrectomy. These interesting observations have not been explained.

Every one now recognizes that the obvious clinical counterparts of experimental renal hypertension are rare. Occasional patients with arteriosclerotic obstruction of the renal arteries, perinephric hulls, Wilm's tumors compressing the renal parenchyma and the like are seen, but the average hypertensive patient has none of these. Is there, then, any evident similarity between the kidney in the human hypertension and that in the experimental form? It has seemed to Corcoran and me that the interstitial fibrosis of the pyelonephritic kidney might mimic the cellophane perinephric hull by reducing the pulsation of the kidneys. But in early hypertension the changes in kidneys, if any, have eluded us all. Because of the pronounced somatic expression of nervous overactivity in some patients, the opinion exists that in some unknown manner the kidneys are stimulated to produce pressor substances. Kottke, Kubicek and Visscher's²⁰ experiments on stimulation of the renal nerves suggest that hypertension occurs only as long as the nerves are being stimulated. That any such mechanism exists in patients is pure conjecture.

MECHANISMS OF RENAL HYPERTENSION

Experimental renal hypertension more closely simulates essential hypertension in human beings than any other experimental form. This is good reason for its having been more extensively studied than others. A danger lurks in the use of the term "renal," because of the implication that the kidneys alone supply the mechanism for elevation of arterial pressure to abnor-

mal heights. While the kidneys may be accorded primacy in some, they could not produce hypertension without active participation of the circulation with its multiple controls.

Hypertension can be produced either by severing the carotid sinus and aortic depressor nerves or by producing cerebral ischemia along with medullary stimulation. The hemodynamic changes in neither are identical with those in the usual patient with essential hypertension, although certain similarities exist. For example, arterial pressure is in large measure determined by heart rate in both animals after sinoaortic nerve section just as it is in some patients with early essential hypertension. However, the differences rather than the similarities are at present the more evident.

NERVOUS PARTICIPATION

The part played by the renal nerves has of late caused some interest and indeed some concern. Observations made in both hypertensive patients and dogs showed no special participation of these nerves in the mechanism of renal hypertension. Kottke, Kubicek, and Visscher²⁰ found persistent hypertension in dogs as long as the renal nerves were stimulated continuously by indwelling electrodes. Every one hoped that the hypertension would persist after discontinuation of the stimulation, but it did not. Even more recently, Trueta²¹ made the interesting, if somewhat imaginative, claim that hypertension is due to shunting of blood through juxtamedullary glomeruli via sluiceways more directly into the venous system, so eliciting cortical ischemia. This shunting seems to be under nervous control. Strongly against this notion is the fact that Bradley²² found normal extraction percentages in the kidneys of hypertensive patients. Further, there is no substantial current evidence indicating that cortical ischemia is in itself a cause of hypertension.

Thus, in animals with experimental renal hypertension, severing the renal nerves neither lowers blood pressure nor prevents elicitation of hypertension. Splanchnic nerve section, anterior nerve root section and even "total" sympathectomy with cardiac denervation are all without decisive influence on the elevated blood pressure. Destruction of the cord leads to profound fall in blood pressure, but, if the animals can be kept in a fair state of health, hypertension returns, but not to its preoperative level. Whatever the mechanism, destruction of the cord affects blood pressure significantly, while sympathectomy does not, in animals with renal hypertension. Here, there is both a similarity to and difference from patients with hypertension. It is not clear what function the pressor substances found in the cerebrospinal fluid have in the genesis of neurogenic hypertension. I²³ found such a substance in 1937 and Raab²⁴ more recently. Raab reviewed admirably the nature of this problem.

ENDOCRINE PARTICIPATION

Systematic experiment shows that the removal of the entire pituitary gland in both rats and dogs is associated with fall in blood pressure, but usually not to

wholly normal levels. The fall is slow, suggesting an indirect rather than direct participation in the mechanism controlling blood pressure. Removal of the posterior pituitary has no effect, while loss of the anterior reproduces completely the arterial pressure changes of total hypophysectomy. After the fall in blood pressure, according to the careful work of Anderson, Page, Li and Ogden,²⁵ it may be again raised to the original hypertensive level by administration of the pure adrenocorticotrophic hormone of Li and Evans.

The view that the adrenal glands are more directly concerned in the mechanism of hypertension comes from the early observations on experimental renal hypertension that removal of both glands causes a fall in arterial pressure to normal or even below. Administration of salt is insufficient treatment to restore the hypertension. Lewis and I have studied the effect of a variety of other treatments. Compound A acetate plus desoxycorticosterone acetate kept the blood pressure at a level as great as or greater than before adrenalectomy. Desoxycorticosterone acetate alone over an extended period led to severe attacks of hypoglycemia, but arterial pressure tended to remain elevated in the salt-fed animals.

Studies of Gaudino²⁶ suggest that the fall in blood pressure, in rats at least, is associated with reduction of renin substrate in the blood. This is the protein substrate on which renin acts to produce angiotonin. In normal rats, bilateral adrenalectomy produces a sharp fall together with some reduction of blood pressure. In only 5 of the 10 hypertensive rats did substrate fall, despite reduction to normal in arterial pressure. Treatment of the adrenalectomized normal rats with desoxycorticosterone acetate restored the renin substrate to normal concentrations and arterial pressure to normal. Similar treatment of the hypertensive adrenalectomized rats reestablished the hypertension. No measurements of the substrate appear to have been made in the latter group.

Lewis and Goldblatt²⁷ claimed to have demonstrated complete disappearance of substrate in the blood of untreated adrenalectomized dogs. Adequate therapy with adrenal cortical hormones or desoxycorticosterone acetate resulted in a return to normal level. Full details of these experiments reported in 1942 as yet have not appeared.

This explanation of the mechanism of adrenal participation in hypertension is attractive indeed, but closer scrutiny of the results so far published is not encouraging. The method for the determination of substrate is crude in the extreme, and the results with hypertensive rats shows only one half of them exhibiting a fall in substrate while all show a fall in pressure.

Finally, the observation that desoxycorticosterone acetate acts on the metabolism of a protein is entirely foreign to what is known of this substance. There is good evidence to show that desoxycorticosterone acetate is without action on protein synthesis. That it should act alone on renin substrate is unlikely. Therefore, until more and better evidence is available, it seems necessary to suspend judgment on the Lewis and Gold-

blatt and Gaudino evidence as providing the solution to the vital problem of how the adrenal glands participate in the mechanism of hypertension.

Since Selye was able to produce nephrosclerosis and hypertension by administration of anterior pituitary or desoxycorticosterone acetate, it is natural to suppose a similar mechanism in human hypertension. Desoxycorticosterone acetate occurs in minute amounts in the normal human adrenal cortex. Even this small amount present over long periods of time might produce vascular change. There are obviously many other possibilities for participation in the mechanism of hypertension by both pituitary and cortical steroids. At present, there is no evidence on which to form any opinion as to the probability of any of them.

Perera²⁸ described the occurrence of Addison's disease in a patient with essential hypertension which throws some light on adrenal participation in the latter. While the patient was receiving desoxycorticosterone acetate, the pressure was persistently elevated. Replacement therapy with salt alone, even though the patient was in electrolyte and water equilibrium, resulted in a drop of blood pressure to normal. The results parallel those described previously for animals with experimental hypertension. Rigid restriction of sodium chloride from the diet in patients obliterates the pressor action of desoxycorticosterone acetate which follows its injection into those receiving salt. Hypertensive persons seem to be more susceptible to desoxycorticosterone acetate than normal persons, because the twice daily injections of 5 mg. produce a rise in both systolic and diastolic pressures in the former but not in the latter. The rise could not be attributed to salt and water retention alone, since comparable retention occurred in normotensive persons (Perera and Blood²⁹).

HUMORAL PARTICIPATION

Contemporary thinking on humoral participation in the mechanism of renal hypertension exhibits dichotomy. Some believe that, as the result of changes in the character of the blood flow within the kidneys, renin is liberated from the tubular cells to react with renin substrate to produce angiotonin or a protein-bound prototype. Others think that hypertension is the result of ischemia of the kidneys of a degree sufficient to provoke the production of pressor amines, of which hydroxytyramine is the prototype. Holding to the former opinion, I shall emphasize that view.

As Corcoran and I³⁰ showed in dogs made hypertensive by clamps on the renal arteries or by cellophane perinephritis, hypertension could be produced without more than transient reduction of renal blood flow. In patients with essential hypertension, Goldring and Chasis³¹ found reduction of blood flow only late in the course of the disease, not during its initiation, a fact we have repeatedly confirmed (Corcoran, Taylor and Page³²). It is hard, therefore, to understand how hypoxia of sufficient degree could occur to set in motion the enzymatic degradation of amino acids to pressor

amines and suppress the destructive action of the amine oxidases.

The renal vasopressor system, made up as it is of renin, renin substrate and angiotonin, seems to me the one more likely to be concerned in the genesis of experimental renal hypertension. Renin is a proteolytic enzyme contained in the tubular cells which acts on an α_2 globulin produced by the liver and contained in the blood. The product of the reaction is angiotonin (hypertensin), a polypeptide which is highly pressor in its action. It is possible that in the body angiotonin is combined with protein and is split off only by such treatment as precipitation with alcohol or heat to produce the angiotonin as it is known at present. Aside from conjecture, there are two bits of evidence which suggest this possibility. Some years ago, my co-workers and I found a protein-like vasoconstrictor substance in the blood of hypertensive and normal patients and dogs as demonstrated on the rabbit's ear vessels perfused with plasma. The possibility of the presence of a vasoconstrictor substance resulting from coagulation of the blood prevented us from being certain of our results. The problem is again under active investigation, now that Rapport, Green and I³³ have found a method of inactivating the serum vasoconstrictor (crystalline "serotonin").

The second bit of evidence is more convincing and comes from the work of our former colleagues Helmer, Shipley and Kohlstaedt.³⁴ They found that plasma from sick or shocked animals, or ones given injections of crude extracts of kidney, contains a pressor substance which when injected into nephrectomized cats produces a sustained rise in blood pressure. The material was partially purified by ammonium sulfate precipitation. Its nature is not as yet elucidated. Whether such a substance occurs in hypertension is not known, and its study will be awaited with keen interest.

A further dichotomy of thought has occurred, largely, I suppose, because of the difficulty of finding sufficient quantities of renin in peripheral blood to account for the rise in blood pressure. Thus Ogden³⁵ has marshalled the evidence in a stimulating fashion to suggest that during the first weeks of experimental renal hypertension the humoral mechanism is chiefly responsible, displaced later by the vasoconstrictor action of the nervous system. Another view reverses this sequence, giving primacy to the nervous mechanism, the humoral prevailing later. The evidence for either view is not strong.

One must recognize, as Leloir, Munoz, Taquini, Braun-Menendez and Fasciolo³⁶ originally showed, that shocking operations cause the immediate liberation of renin into the blood stream, and therefore it is not surprising that the enzyme should be found in excess in peripheral blood after operation on the kidneys to induce hypertension. As we have seen, renin itself is not a vasoactive substance; it is merely one component of a complex system yielding vasopressor substance. Its measurement out of the framework in which it works, i.e., the highly artificial in vitro environment, has to me only limited significance. Could the

effector substance itself be measured, whatever it be, the results would be far more apposite. As has been repeatedly emphasized, the physiologic mechanisms of hypertension are multiple and interconnected. Just so are the chemical ones. Their simplification on the basis of ignorance of their complexity can lead only to premature apostasy.

Thus renin appears early in the blood after operation on the kidneys, and from this it is argued that the hypertension is initiated by the renal vasopressor system. After a week or so, renin disappears from the blood as measured by contemporary methods, hence, the argument runs, nervous control has taken over. The argument exemplifies the complexities of humoral control and the inadequacy of present evidence to offer satisfying answers to the problem of its participation in the regulation of blood pressure.

Most of the known pressor agents as causes for hypertension are ruled out by their pharmacologic properties. For example, many elevate arterial pressure by increasing cardiac output, a phenomenon not consonant with the hemodynamics of essential or experimental renal hypertension. Many of them produce severe symptoms, again not in accordance with observations on early essential hypertension. For these and other cogent reasons, angiotonin seems from the testimony of brief experiments in both human beings and animals most nearly to reproduce the mechanism which elevates arterial pressure. Yet the reproduction is not sufficiently perfect to be certain that it, in its present form, is the one solely involved.

This is a highly complex problem which will find no easy solution. Yet let no one doubt that methods are not now at hand for its solution. It is not for lack of knowledge that one must wait; it is for lack of hands and heads with which to do it.

THE VASCULAR SUBSTRATE

Investigation of the factors which control the responsiveness of the blood vessels to stimuli has not progressed to the point clarifying the problem of the state of the vessels in hypertension. Actually, only a vague directional trend is in the process of being established—one of great physiologic interest, but one not yet shown to be apposite to the hypertensive state.

With Taylor and Reinhard,³⁷ I have studied this problem for several years, it being our special concern during the war years because of its applicability to the problem of shock. Animals and man in deep shock show greatly reduced pressor and depressor responses to chemical stimuli such as epinephrine and angiotonin. Supposedly normal, anesthetized animals exhibit widely differing responses from day to day and even during the same experiment. Significant average responses were obtainable only after study of large numbers of animals. Thus, the blood vessels or the stimuli or both must be highly variant.

The nervous system plays an important part in the control of vascular responsiveness. Injury to it temporarily reduces responsiveness, while its rapid complete destruction enhances responsiveness. Thus section of the cord at the sixth cervical segment and destruction caudad yield a preparation that for days or weeks is highly sensitive to vasoactive substances. It is made much more sensitive by denervation of the carotid sinus and vagotomy. Administration of tetraethylam-

monium chloride (T.E.A.) usually further enhances the responsiveness, but only slightly. The sympathetic nervous system appears thus to be acting in a strongly inhibitory sense rather than the more usual augmentative role.

As Acheson and Moe³⁸ have shown, tetraethylammonium chloride produces its effect chiefly by blocking transmission through autonomic ganglions. The result of this demonstration has been the wide use of tetraethylammonium chloride as a diagnostic and therapeutic agent in clinical medicine, especially by Lyons, Moe and Hoobler and their groups.

Our interest began when we found that administration of large doses of the drug greatly augmented the vascular responsiveness to a variety of vasoactive substances, such as angiotonin, barium chloride, epinephrine and arterenol³⁹ (3,4-dihydroxyphenylethanolamine), and that in certain circumstances the lost responsiveness caused by repeated injections of renin was restored.^{37b} I would agree with Moe that the most probable explanation of this truly remarkable action is based on release of all inhibitory nerve impulses.

As it concerns hypertension, the fact emerges that normal animals are converted by repeated doses of tetraethylammonium chloride from "depressor" preparations to "pressor" ones in which the pressure rises instead of falling when tetraethylammonium chloride is given. The first dose of tetraethylammonium chloride gives a large fall, but on repetition less and less occurs until nothing but pronounced rises occurs. Part of the rise is probably due to adrenal stimulation as Acheson and Moe suggest, for as large pressor responses in adrenalectomized dogs were not observed. Destruction of the spinal cord itself is sufficient to insure only pressor responses. If the adrenal glands are removed from such animals, a pressor response is still obtained. Such animals are so exquisitely responsive to pressor stimuli that they remind one of the beginning phase of hypertension in some patients. Removal of both kidneys still further increases responsiveness, especially to renin and angiotonin. The effect is not immediate, however, a day at least being required, suggesting the possibility that a sensitizing agent is being retained or not destroyed, the prototype of which well may be the tetraethylammonium ion.

Removal of the liver, in contrast, greatly depresses vascular responsiveness. Despite the fact that arterial pressure may be temporarily well maintained, the response to a variety of agents is damped. For reasons not at all clear, tetraethylammonium chloride does not exert its augmenting action in any significant degree in these hepatectomized animals.

With only these crude facts at one's command, it is possible greatly to depress or abolish responsiveness or greatly to heighten it. If such factors participate significantly in the hypertensive patient, and surely they may, the amount of a pressor substance or nerve stimulus required to elevate arterial pressure would be irrevocably tied to the responsiveness of the vascular tree. Lacking the latter datum, even the accurate estimates of the amounts of pressor agents lose significance to an alarming degree.

Several years ago my co-workers and I found that plasma of hypertensive dogs exhibited greater than normal vasoconstrictive power when perfused with plasma through rabbit's ear vessels. As we pointed out, the amount was in no way proportional to the

height of the blood pressure. Further, the results are complicated by the presence of the vasoconstrictor which forms when blood clots. Thus any method in which pressor agents are sought in blood is subject to an incredibly large number of pitfalls. It is only recently that we have begun to appreciate the complexity of the depressor-pressor systems of the blood and to overcome the naïveté of our approach a decade or more ago. Whatever the assurance of our colleagues, our view has turned to one of humility before the complex equilibria of vasoactive substances in the blood and their interaction with the changing reactivity of the blood vessel substrate on which they act. The kidney is only one part of this relationship and, though of great importance, should not be given primacy to the exclusion of other controlling factors.

To return to the problem of vasoconstrictor in the hypertensive patient's blood, Solandt, Nassim and Cowan³⁹ found greater rises in arterial pressure when hypertensive dog's blood was cross transfused than when a normotensive dog's blood was used. In patients, according especially to Prinzmetal, this is not the case. Taylor, Prince and I have studied this problem recently. We found no difference between hypertensive and normal dogs on cross circulation. A non-epinephrine-like substance appears in the blood, especially in hypertensive dogs but by no means limited to them. The irregularity of its occurrence has doubtless contributed greatly to the current confusion. One must therefore await further evidence.

When the kidneys of dogs with long-standing hypertension were removed, the blood pressure did not return to normal as had been shown by Pickering⁴⁰ and others. Further, we found that the plasma retained its vasoconstrictor properties until the death of the animal. This, in conjunction with the fact that the blood vessels in such circumstances became more sensitive to vasoactive humoral agents, might possibly explain persistence of the hypertension. Indeed, some of the animals became so sensitive that normal amounts of pressor agents might have accounted for hypertension.

CONCLUSION

To those not deeply imbued with the sense of urgent need for the solution of the problem of hypertension, many of these studies must seem trivial or inadequate. So much so that to some the endeavor hardly seems worth pursuing. To the optimist, the price of success is trouble. That there is plenty of the latter all could agree. Whether their resolution will lead to success remains for the future to decide.

ABSTRACT OF DISCUSSION

DR. CARLOS JIMENEZ DIAZ, Madrid, Spain: My co-workers and I are studying the mechanisms of regulation of the stimuli causing hypertension. We have utilized the pressor effect of electric stimulation of the central end of the cut vagi. This effect is visible even after the hypophysis has been removed and also after a bilateral nephrectomy and adrenalectomy, but disappears when the cord is sectioned. One must accept that the stimuli pass to the nervous centers and descend to the vascular innervation by the spinal cord and sympathetic fibers. In a second series of experiments on crossed blood circulation we found that excitation in donor dogs produces a hypertensive answer in the receptor. We assume that the nervous action

on the arterial wall elicits the production of a chemical tonogenic substance. We have made also experiments on a divided dog, in which the superior and inferior parts of the dog's body are connected only by the spinal cord. Circulation of the superior part is maintained by his own heart, and the inferior is perfused by a pump. As we excite the vagi we increase the blood pressure not only in the superior but also in the inferior perfused part. The most interesting observation is that if we perfuse not with dog's plasma as in the earlier experiment but with saline serum the stimulation does not produce hypertension in the inferior part of the dog's body. The inference is: (1) that nervous action on blood pressure is initiated by the production of a pressor substance and (2) that these substances arise from the action of some secretion of the arterial wall on a preexisting substance in the blood plasma. Indeed we have prepared extracts of arterial wall, and we made incubation with the plasma's renin-substrate; the results are clear and constant: extractions of arterial wall are without effect, and when incubated with plasma the pressor effect is exactly the same as with renin plus renin-substrate. These experiments can bring new understanding of the problem of hypertension and indicate the main part that, in the regulation of blood pressure, in addition to other factors, a true internal secretion of the artery may play. It is possible that arterial hypertension, as other constitutional diseases, can be considered in the future as a variation in activity of enzymatic systems.

LOW SODIUM CHLORIDE DIETS IN HYPERTENSION

Effects on Blood Pressure

St. Louis

The present study was made in an attempt to evaluate the effects of restriction of dietary sodium chloride on the blood pressure of hypertensive patients. For many years, diets low in sodium chloride (salt) have been advocated as a rational measure in the treatment of arterial hypertension. Their use, however, has not been altogether accepted, although in occasional patients striking reductions in blood pressure have been reported.¹ A critical evaluation therefore seemed necessary under as controlled conditions as possible, with the effects of hospitalization, bed rest, sedation and psychotherapeutic influences eliminated so far as practicable.² In planning our previous study² and the observations reported herein, we have selected low salt regimens which can be observed by a patient at home with relative ease.

During the course of this study, it soon became evident that beneficial results on the level of blood pressure did not occur in most hypertensive patients when other factors were controlled. This was in accordance with the past experience of one of us (H. A. S.). On

the other hand, it also became apparent that some patients were benefited insofar as their blood pressures were concerned by the restriction of salt, and it appeared important to attempt to differentiate the group favorably affected from that not affected. Since it was suspected from clinical observations that patients who would respond to the restriction of salt in their diets had certain characteristics in common, some patients were selected for this study because they exhibited these peculiarities. Therefore, the results here reported can in no way be examined statistically, as they involve a larger proportion of subjects whose blood pressures were influenced by salt restriction than would be found in the general hypertensive population.

METHODS OF OBSERVATION

Twenty-two patients were selected for study and admitted to a metabolic ward. In most instances, no changes in regimen were made for two to six weeks, in order that the blood pressures could be measured under controlled conditions. Measurements were made in the morning before arising and in the afternoon after half an hour of bed rest. The averages shown in table 1 were made from all readings during seven to ten days at the end of the control period and at the end of the period of restriction of salt. Most patients were ambulatory on the ward; a few remained in bed, but this factor was constant throughout the experiment. Diets consisted of the usual hospital menu, but a few patients ingested diets restricted as to salt during the control period with salt added in the form of capsules. Patients were not led to believe that the restriction of salt would be in any way beneficial, nor were they informed of the levels of their blood pressures.

The amount of sodium in the diet was calculated from standard tables³ and was expressed as sodium chloride. In 7 cases a diet composed of rice and fruit juices was used (Kempner diet⁴); in the others, protein was restricted only so far as was made necessary by salt restriction. Lately salt-poor milk (Ionolac,[®] Mead Johnson and Company) was used to increase the protein intake. Sodium chloride in the diet was restricted to 0.5 Gm. per day in 9 cases, to 1.0 Gm. in 12 and to 2.0 Gm. in 3.

RESULTS

Effects of Sodium Chloride Restriction on Blood Pressure.—In 13 of 22 cases, changes in average diastolic blood pressure of 9 mm. of mercury or less were observed after restriction of dietary salt (table 1). In 3 of these cases, the systolic blood pressure fell from 21 to 25 mm. of mercury and in 1 other, 15 mm. of mercury. No other effect on the progress of the disease was noted which could not be explained on the basis of rest and hospitalization. The conditions of 3 became worse. One (case 3), with poor renal function, died, probably as a result of salt deficiency initiated by the diet. In 1 (case 11), the clearance of urea fell from 33 to 15 per cent of normal and in another (case 9) fresh hemorrhages appeared in the eye-grounds. Six of the patients received diets containing 0.5 Gm. of sodium chloride, 5 received 1 Gm. and 3 received 2 Gm.

In 9 cases, the average diastolic blood pressure fell from 14 to 36 mm. of mercury, reaching levels below 100 mm. in 6 and below 90 mm. in 2. The systolic pressure likewise fell from 60 to 19 mm. of mercury (table 1). In most of these cases, symptomatic improvement occurred. Otherwise, changes in the status of the disease were not evident. Three of the 9 received diets containing 0.5 Gm. of sodium chloride,

and 6 received 1.0 Gm. On the whole, this group represented patients in less severe stages, 7 of them exhibiting minimum changes in their ocular fundi and all manifesting good renal function. The diastolic pressures of only 4 were 115 mm. of mercury or more at the end of the control period, while of the group which did not respond, all but 2 had diastolic pressures at this level or above.

Analysis of Patients Responding to Restriction of Salt.—Those patients who responded by a significant fall in blood pressure to restriction of salt were

mon to many and were not present in other cases. In addition, the response of their blood pressures to salt restriction usually occurred in a matter of a few days, and when salt was added to their diets, as in 4 cases, blood pressures became definitely elevated to or nearly to the control values.

The 6 patients in question were all women and all obese. They sometimes gave a history of obesity appearing comparatively rapidly, at puberty or after childbirth. Characteristic of these patients was the difficulty they experienced in attempting to lose weight.

examined in an attempt to determine the presence or absence of common characteristics, or of differences from those who did not respond. Of the 9 favorably affected, 2 (cases 14 and 16) were in milder stages of the disease, one of them being a highly suggestible psychoneurotic person. One (case 15) appeared to be affected only after a relatively prolonged period (three weeks) on the diet, and in 1 (case 14) the later addition of salt had no unfavorable effect. It is uncertain, therefore, that salt restriction alone produced the changes observed. The other 6 appeared to belong to a definite but not completely defined group in that certain clinical and laboratory observations were com-

Their histories appeared to attest the ineffectiveness of reducing diets, and we have found that true in general. Low caloric diets used in the hospital seemed to be less effective in these persons than in other obese persons. Yet their basal metabolic rates were not abnormally low. The obesity was confined to the trunk, face and proximal parts of their extremities. Pale striae were present in 3 and brownish striae in 1. Hirsutism of some degree was found in 3, in 1 (case 18) requiring biweekly shaving of the face. Menstruation was irregular in 3. Four complained of a tendency to ecchymoses, minor trauma producing discolored bruises. In 2 cases a mottled dusky cyanosis of the extremities was noted.

Neither acne nor polycythemia was present. Oral glucose tolerance tests showed a diabetic type of curve in 3; in 1 it was normal, and in 2 it was not measured. One patient (case 17) had received insulin previously for glycosuria and hyperglycemia. All complained of moderate to severe headaches, localized in the occipital region in 4, in the frontal in 1 and in the vertex in 1 (table 2).

Albuminuria was absent, although in at least 3 cases blood pressure was at relatively high levels and the disease had been present for a considerable period of time. Abnormal microscopic elements in the urine were few or absent. When the intake of fluids was compared with the urinary output, 3 of these patients appeared to show usually a relatively low urinary

measured, the ratio of sodium to chloride was lower than that found by Selye⁵ in many hypertensive patients. In 3 patients in the group not responding to a low salt regimen, this ratio was elevated above 1.44, Selye's upper limit of normal.

Five milligrams of desoxycorticosterone acetate was injected intravenously or 10 mg. intramuscularly in 4 of these patients. These single injections were followed in all cases by prolonged elevations of the blood pressures, lasting from one to three days. Such a response is unusual, as most hypertensive persons will not derive such a long-sustained elevation of blood pressure from a single dose of this substance.

The general body configuration of these patients is worthy of comment. It resembles in some respects

† Hirsutism—on face, chest or abdomen.

‡ By oral method.

§ Low urine output means that there was considerable discrepancy between the intake and output of fluids for periods of many days at a time, the urine volume being one quarter to one half of the intake. There was no correlation between this finding and the season of the year.

|| Obesity of trunk, face and proximal parts of extremities ("buffalo" type).

¶ The patient's blood pressure became significantly elevated above control values, after one injection of 5 mg. desoxycorticosterone acetate intravenously or intramuscularly and remained elevated for one to three days.

See text.

volume. This condition was not consistent throughout the period of observation, but it was noted that for many days the output of urine would vary from about 600 to 800 cc. per day, while the intake was 2,000 cc. or more. In 1 (case 22), who was carefully studied by control of the intake of fluids, the urine output remained below 800 cc. a day for thirty-four days, often being below 500 cc., and did not rise when the fluid intake was increased from 800 to 2,000 cc. per day. There was no gain in weight despite this discrepancy; the patient manifested profuse sweating. Antidiuretic substance was found in her urine.

In 3 cases, plasma sodium determinations were made and were within normal limits. Plasma chloride levels, however, appeared to be slightly higher than are usually found in this laboratory, varying from 105 to 110 milliequivalents per liter. In the 3 cases in which it was

that seen in Cushing's syndrome. When other suggestive signs and symptoms of Cushing's syndrome were looked for, some of them were found; but in no case were all of the classic observations of this condition present.

COMMENT

From a review of our cases, it would appear that restriction of sodium chloride in the diet, either by the use of the "rice diet" of Kempner or by other means, is usually ineffective when the condition is advanced and therapy becomes mandatory. In one type of case, however, restriction of sodium chloride appears to be definitely beneficial with respect to the level of blood pressure. In this type, restriction of salt appears to lower blood pressure when other factors are controlled,

5. Selye, F. L.: Biochemical Changes in Hypertension, *Canad. M. A. J.* 57: 325-330, 1947.

and addition of salt to the diet appears to raise it. The clinical observations in this group of patients are suggestive of an alteration in some of the functions of the adrenal cortex, although laboratory confirmation of such disturbances is so far lacking. Such a disturbance, if present, is not advanced enough to produce the classic observations of Cushing's syndrome, although many of its manifestations seem to be present to some degree. The condition in these cases has been called "pseudo-Cushing's syndrome."⁶

In view of the apparent differences in this obese group of patients from the usual patients with arterial hypertension, it is possible that these patients suffer from a different condition of which hypertension is only one manifestation. Once aware of this condition, one finds it relatively easy to identify. Recognition makes dietary restriction of salt of more certain benefit to the

changes which had occurred were somewhat reversed. Other influences than dietary ones cannot, therefore, be excluded in these 3 cases.

In general, every effort was made in this study to exclude the effects of influences other than dietary ones. One of these, hospitalization, has proved a very significant one in some patients (table 3).² It has therefore been our practice to require a control period in the hospital of about a month's duration before instituting any therapeutic procedure. In only 3 patients (cases 13, 20 and 22) was no control period used, although observations on them in the outpatient department had indicated sustained high levels of blood pressure for long periods. In 3 cases the control period was two weeks, and in the remainder (9 in the first group and 7 in the second, table 1) it lasted three to six weeks or more. If this relatively long period had not been used, the

‡ Studied for effect of hospitalization only.

patient and avoids for the patient the inconveniences of trial and error methods of dietary management.

The other patients who responded to the restriction of salt (cases 14, 15 and 16) either exhibited considerable susceptibility to psychotherapeutic influences, being easily suggestible, or were in mild stages of the disease. The response of their blood pressures to salt restriction occurred after a later interval than it did in the "pseudo-Cushing" group. In 1 (case 14), the addition of salt to the diet had no effect; in another,

diets would have appeared beneficial in 5 of the group in which a poor response was noted, and more beneficial in 3 of the others. It seems possible, therefore, that some reports of good results accruing from low salt diets have not taken these other influences into account.

SUMMARY AND CONCLUSIONS

Twenty-two patients with hypertension were placed on diets low in sodium chloride in the hospital in an attempt to evaluate the effects of such diets on the levels of their blood pressure. The effects of hospitalization and psychotherapeutic influences were controlled so far as possible.

In 13 patients, most of whom exhibited the disease in its severer stages; the response to salt restriction was poor. Three additional patients with milder forms of the disease manifested a lower level of diastolic pres-

6. By Dr. Willard M. Allen, of Washington University School of Medicine. It is probable that these cases are similar in many respects to those reported by Herrick, W. W.: Hypertension and Hyperglycemia, J. A. M. A. 81: 1942 (Dec. 8) 1923. In a review of 218 cases of "essential hypertension," Schroeder and Steele noted 7 cases which fitted into this category and 7 other obese women whose hypertension began with the menopause. In addition, 2 obese women exhibited elevated basal metabolic rates without hyperthyroidism. Some of these were benefited by restriction of dietary salt. Schroeder, H. A., and Steele, J. M.: Studies on "Essential" Hypertension: I. Classification, Arch. Int. Med. 64: 927-951 (Nov.) 1939.

sure; in 1 of these the change which occurred was not reversed by the addition of salt to the diet.

A group of 6 female patients are described who exhibited obesity of a characteristic distribution, and some but not all of the signs of Cushing's syndrome. In these, levels of blood pressure appeared to be directly related to the intake of sodium chloride, being lower when salt was restricted and higher when it was added. These patients probably suffer from a disturbance of which arterial hypertension is only one manifestation. It is suggested that there is an alteration of some of the functions of the adrenal cortex in such persons. In general, when the disease was relatively advanced and treatment was mandatory neither restriction of salt nor the rice diet appeared to be of much benefit.

ABSTRACT OF DISCUSSION

DR. DAVID AYMAN, Boston: Dr. Schroeder has presented one of the first series of controlled—although limited in number—observations on the effects of the rice and salt-free diets. It appeared clear that Kempner's studies, as he reported them, did not include the controls necessary in any careful evaluation of blood pressure. The universal demand for the diet by patients followed the unfortunate newspaper publicity which greets the announcement of any new method or treatment, so that patients have placed themselves on the diet without medical care or forced physicians to put them on the diet. Kempner's methods in general consisted of brief periods of control before the diet, so that a large number of his patients have been placed on the diet either at once or within a few weeks after arrival at Duke University. Dr. Schroeder has attempted to avoid this source of error by waiting three or four weeks before starting the diets. However, even such a period of waiting before treatment is not adequately long. Dr. Schroeder recognized this when he demonstrated in several patients that hospitalization alone caused significant drops in blood pressure, in 1 case to normal levels. It follows, therefore, that if all patients had been given the diet after thirty days of hospital rest and observation, further drop in blood pressure might well have occurred in some additional patients if he had waited ninety days before introducing the diet. Dr. Schroeder modified Dr. Kempner's study a bit by using a nightly barbiturate. This, together with a quiet hospital environment, might be enough gradually to lower blood pressure by progressive relaxation. The study that Dr. Schroeder has today presented is clearly of a small number of patients. I think, therefore, that on the basis of such a small number of patients it is unwise to estimate even roughly that blood pressures in 10 per cent of hypertensive patients will drop to normal levels on a salt-free diet. The effect of rapid weight reduction on blood pressure, as well as any specific diet effect, is involved in the studies of Kempner and Schroeder. Kempner admitted that it is common to have decided weight loss in the first twenty days of the diet. Schroeder's cases show the same weight drop. I would like to ask Dr. Schroeder whether he noticed any decreases in heart size, favorable changes in electrocardiograms or improved changes in the fundi, all of which Dr. Kempner frequently found with the rice diet. The diminution in heart size and improvement in electrocardiograms, nonprotein nitrogen levels and cardiac state, as reported by Kempner, merit some mention and some explanation. In Dr. Kempner's papers the striking effects on blood pressure, heart size, electrocardiographic observations and fundi, have been most often in patients with congestive heart failure or nephritis. In these two conditions the rice diet, with its restrictions of sodium and protein, is merely a more stringent form of low sodium and low protein diets already used for heart failure and nephritis.

DR. MILTON LANDOWNE, Chicago: When a patient is put in a hospital it may take a while for his pressure to become "stabilized," and during that period his blood pressure may fall. The reduction of blood pressure to a more basal level by hospitalization alone might also have been accomplished

by some other form of therapy for the ambulatory patient. Once the pressure has been lowered by hospitalization, however, the other therapy may not reduce it further. That may have been partly in the mind of Bryant and Blecha when they reported that a majority of ambulatory patients on a very low salt diet had a reduction of blood pressure. Because of their report my co-workers and I undertook to study a small group of patients in the clinic rather carefully, and we attempted to control the therapeutic and psychotherapeutic effects of placing them on a rigidly restricted salt diet. We put these patients on a diet calculated to be adequate except for its sodium content of less than 300 mg. per day. In addition, we gave these patients medication consisting either of lactose or of 4 Gm. of sodium chloride a day given in identical manner. We did twenty-four hour urinary analyses for sodium and creatinine once a week as a check on how well the patients were following the diet. I do not propose to report here on the results of our study, but will mention two pertinent points: First, only 1 out of 3 patients whom we had expected to be on the diet stayed within the limits of the diet as we defined it. Therefore, without urinary checks, one cannot assume that the patient is following a salt-restricted program. There is no report from the Michigan group as to how many of their patients followed the diet. Our data indicate that 1 out of 3 patients whom we put on a diet restricted in sodium to considerably less than 0.5 Gm. of sodium per day actually followed that diet to that degree. Second, while we did find an occasional patient whose blood pressure fell during the period of effective sodium restriction, there was certainly no overwhelming difference between the control and the experimental subjects when the variable factor was entirely or largely limited to the salt received.

DR. FREDERICK M. ALLEN, New York: Experiments which seek to extenuate the former error of denying the pressor effect of salt by depicting it as small invite comments epitomized as follows: 1. Animal experiments conclusively prove pressure elevation by salt. 2. Allen-Sherrill (1922) excluded psychic, weight, protein and other factors in 280 cases during four years. 3. Even in this first use of diets capable of producing salt deficiency, supervision prevented dangers. 4. Brief observations on a few patients of the class recognized as refractory by myself, Kempner and Grollman establish no scientific conclusions for the whole subject. 5. Just as in diabetes, failures in worst cases do not invalidate diet principle. 6. My distinction, twenty-two years ago, between symptom and disease of hypertension explains benefits not measured merely by pressure reduction and often apparent after years in initially refractory cases. 7. Symptomatic variations, physical and psychic influences must be weighed against death rate unaltered by symptomatic palliations, and rarity of hypertension among the insane with utmost excitations and depressions. 8. Preliminary rest makes pressure reduction in subsequent brief diet experiments appear as small as possible but misses distinction between transitory symptomatic effect and permanent specific diet effect. Diet keeps all but extremely hypertensive patients active and improved. 9. Frequent clearing of retinitis, congestive failure, headaches, dyspnea and other symptoms is unmistakable. 10. Permanent effects are paramount. Though I oppose operation, necessity of evaluating results in chronic disease during many years is recognized by surgeons, not by our medical opponents. Kempner's duplications of my results should prove similarly durable unless superfluous restrictions discourage the necessary lifelong fidelity. 11. I first demonstrated that vascular atony of shock requires sodium chloride solution, not plasma proteins. 12. Selye connects sodium chloride with etiology of hypertension. Therefore, though my research was cut off, I still submit that observations supporting salt restriction are superior in number, duration and validity. Appetizing diet encourages fidelity. Long ago, the public should have been taught to accept diet for hypertension as routinely as for diabetes. The waste of life during the past twenty years may continue for another ten years before all agree. My conclusion, based on unique experience in several thousand cases during twenty-eight years, is that saltless diet, especially when begun reasonably early, can specifically arrest

progressiveness, prevent complications and thus provide the first real control of deaths from hypertension.

DR. EUGENE FOLDES, New York: In regard to the effects of various diets on arterial hypertension, I should like to call attention to the antiretentional dietary which I introduced fifteen years ago. This diet is based on the postulate that the water content of the blood, and thus the circulatory blood volume, vary with the water content of the rest of the organism, so that measures which reduce the water content of the body reduce the circulatory blood volume. The antiretentional diet is further based on the concept that reduction of the circulatory blood volume is followed by reduction of the blood pressure and aims at such reduction of blood volume and blood pressure by the administration of a regimen in which food substances are selected according to their effects on the water and mineral metabolism. Food substances having diuretic action, such as proteins and vitamins, are employed in liberal amounts, while food substances which may lead to liquid retention, such as carbohydrates, fats, sodium chloride and water, are used sparingly. I found this diet effective in many cases of arterial hypertension, and the results were confirmed by others. These therapeutic results, when compared with those obtained by the salt-free and the rice diets, are not unfavorable to the antiretentional dietary. The person suffering from arterial hypertension has functions and needs other than those determined by his blood pressure. These functions and requirements are not always well served by the salt-free and the rice diets. Both of these diets are unpalatable and monotonous. Further, for the human being, sodium chloride is not an indifferent chemical which can be introduced in excessively high or excessively low amounts without damage. The exhaustion and other serious consequences of considerable sodium chloride losses are well known and are further demonstrated in 1 of Dr. Schroeder's cases. Occurrences of pseudo-uremia and influences of sodium chloride deprivation on the carbohydrate metabolism, sexual function and the like should also be considered. As to the rice diet, it is not only salt free but it is also poor in proteins and rich in carbohydrates, a combination which may lead to fatty infiltration of the liver and to all the attendant disturbances. In addition, the rice diet is poor in some of the naturally occurring vitamins and these vitamins cannot be adequately replaced by the administration of a preparation. In contrast, in the antiretentional dietary, consideration is given to the patient's needs other than the regulation of the blood pressure.

QUESTION: Is it possible that salt restriction would be more effective if kept at 200 mg. as outlined by Bryant?

DR. HENRY A. SCHROEDER, St. Louis: The psychotherapeutic influences on the patients were controlled so far as possible, but I will agree with Dr. Ayman that putting a patient in a hospital for three months is a definite psychotherapeutic procedure. These patients were told when they were given rice or low salt diets that this was an experimental procedure, that there had been reports of its being of some benefit, but that we did not know whether or not it was beneficial, and we asked for their cooperation. I would like to stress that in no way have we reproduced the Kempner regimen, which I have no doubt is beneficial in a certain proportion of cases. We merely tried to find out whether the benefit lay in the diet itself or was due to other influences. We were unable to perform a clearcut experiment in any of our patients or to add certain things, like protein, amino acids or sodium, to the diet as we had planned, in order to answer this question. All of our patients lost some weight when on a diet either of salt restriction or of rice. There were changes in the heart size in some, but I believe that changes in heart size or in the electrocardiogram, particularly with respect to the inverted T wave, are functions of the level of blood pressure, and when the blood pressure came down we did notice such changes. Anything which will bring the blood pressure down will often produce these changes; there is nothing specific about the diet. Pyrogens will do it as well. Sympathectomy will do it. Any so-called specific or nonspecific procedure will do it. I think that Dr. Allen deserves great credit for having introduced

the low salt diet into this country in 1922. My own personal interest in salt restriction goes back many years, particularly in regard to its effect on cardiac decompensation. Nothing would please me more than to find that salt restriction was of therapeutic benefit in all cases of hypertension. However, these are our results, and we must interpret them as carefully as we can. We cannot come to the conclusion that there is any specific benefit from salt restriction or from rice in all patients. I think it possible that in patients who do respond to a restriction of salt—and there are some whose response is dramatic—there is different causation, perhaps with more of an endocrine element than a renal or a nervous one. Those with the primary nervous or renal elements do not respond to these regimens as well as do the others. In reply to the question as to whether salt restriction would be more effective if kept to 200 mg. of sodium as outlined by Bryant, which is approximately 0.5 Gm. of salt, that is about the amount of sodium—200 mg.—or which is in the rice diet. We have used the 0.5 Gm. diet frequently.

DIAGNOSIS OF CANCER OF THE LARGE BOWEL

NEIL W. SWINTON, M.D.

HUGH F. HARE, M.D.

and

WILLIAM A. MEISSNER, M.D.

Boston

The diagnostic criteria for advanced malignant disease of the large bowel are well recognized, but the diagnosis of early cancer and the differential diagnosis of benign polyps, diverticulitis and carcinoma require the closest cooperation of the clinician, the radiologist and the pathologist.

In a previous presentation of this subject, comprising a review¹ of 100 cases of cancer of the rectum, 100 cases of cancer of the left colon and 100 cases of cancer of the right colon, it was noted that the chief complaints of the patients could be placed in three groups (table 1):

TABLE 1.—Symptoms of Carcinoma of the Colon and Rectum (300 Cases)*

Symptom	Location of Carcinoma, Percentage of Patients			Total, Per- centage
	Rectum	Left Colon	Right Colon	
Blood in stool.....	86	46	9	46
Altered bowel function.....	79	82	81	80
Abdominal cramps or pain.....	7	77	87	57
None	2	2	3	2.3

* Over 80 per cent of all patients with carcinoma of the colon and rectum complained of rectal bleeding.

SYMPTOMS

1. Rectal bleeding. Over 80 per cent of all patients with malignant disease of the large bowel will have associated rectal bleeding. This is the most significant symptom of cancer of the colon and rectum.

2. An alteration or change in bowel function. The mildly constipated patient who has been taking an

Read before the Section on Surgery, General and Abdominal, at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 25, 1948.

From the Department of Surgery (Dr. Swinton) and the Department of Radiology (Dr. Hare), The Lahey Clinic, and the Department of Pathology, New England Deaconess Hospital (Dr. Meissner), Boston.

1. Swinton, N. W., and Higgenbotham, J.: *The Diagnosis of Carcinoma of the Colon and Rectum*, S. Clin. North America 18: 733-743 (June) 1938.

occasional laxative for years presents little of significance, but if increasing constipation or some other change in bowel function has been noted within recent months, complete studies are indicated.

3. Abdominal pain. This is usually a crampy, colicky-like pain associated with varying degrees of obstruction or nodular extension of the disease.

Fig. 1.—Benign mucosal polyp, showing regularity of gland, maturity of cells and absence of stromal invasion (eosin methylene blue stain $\times 50$).

Ninety-eight per cent of the patients at the clinic with proved carcinoma of the colon or rectum complained of one or more of these three symptoms. There are other signs and symptoms which may be significant. Unexplained anemia is frequently associated with a neoplasm of the right colon. An abdominal tumor may have its origin in the colon without associated colon or rectal symptoms.

Rectal bleeding, the commonest complaint of patients with malignant disease of the colon and rectum, in our experience has been the least well evaluated by physicians. It has too often been casually accepted, probably because it is so commonly experienced. Nearly all of us at one time or another have noted a drop or more of blood on the toilet tissue or in the bowl. Patients, however, are becoming increasingly cancer conscious. The publicity being given the subject of cancer, its early diagnosis and the significance of bleeding from any of the body orifices has resulted in an increase in the number of patients consulting their physician at the first appearance of rectal bleeding. It is of the utmost importance, therefore, to all of us, as physicians, that an adequate examination be made of these patients when they first present themselves.

Any patient with rectal bleeding should be considered to have malignant disease until proved otherwise. Any patient with rectal bleeding, a change in bowel function or unexplained abdominal pain should first have a careful inspection of the perianal area and anal orifice. Anal carcinoma is rare but does occur. A careful digital examination of the anal canal and rectum should follow. Fifty per cent of cancer of the large bowel can be palpated in this manner.

SIGMOIDOSCOPIC EXAMINATION

After digital examination of the rectum, an anoscopic visualization of the anal canal and a sigmoidoscopic examination of the rectum, rectosigmoid and low sigmoid regions should be performed. The origin of rectal bleeding most frequently is in the anal canal. Hemorrhoids, fissures, inflammatory conditions and other common diseases found in this region should be accurately classified. Hemorrhoids and hypertrophied anal papillae or true polyps of the anal canal rarely, if ever, result in malignant degeneration.

The majority of tumors will be found above the anal canal. They may be benign mucosal polyps or malignant tumors (fig. 1). The frequency and significance of benign mucosal polyps of the colon and rectum are not generally appreciated. Swinton and Haug² and Helwig³ reported large autopsy series, giving an incidence of mucosal polyps of the terminal bowel of 7 to 10 per cent for patients dying from all causes. There is an increasing incidence with age and a high percentage of multiplicity of these tumors. The relationship between these polyps and cancer is definitely established. All stages in the development of adenocarcinoma can be demonstrated histologically between polyps of this type and advanced malignant disease (figs. 2 and 3). Mucosal polyps of the large bowel are true tumors and definite premalignant lesions.

The criteria as to when a digital and sigmoidoscopic examination of the terminal bowel should be done are not adequate for the detection of premalignant lesions. Only one third of patients with benign mucosal polyps of the rectum and colon complain of rectal bleeding. A very small number have associated obstructive symptoms.

Fig. 2.—Early carcinoma arising at the base of a polyp, with atypical glands, atypical cells and invasion of stroma (eosin methylene blue stain $\times 50$).

It is our firm conviction that, if large numbers of these premalignant lesions are to be discovered, not only must every patient with any symptom referable to the

2. Swinton, N. W., and Haug, A. D.: The Frequency of Precancerous Lesions in the Rectum and Colon, *Lahey Clin. Bull.* 5: 84-88 (Jan.) 1947.

large bowel be carefully investigated but sigmoidoscopic examinations must be a routine part of every complete general examination. Only when a sigmoidoscope is considered as important a part of one's diagnostic equipment as the stethoscope, vaginal speculum, laryngoscope and otoscope will large numbers of these tumors be found and an appreciable number of patients saved from development of cancer.

Fig. 3.—Adenocarcinoma, moderate malignancy, arising in mucosal polyp (eosin methylene blue stain X 50).

DIFFERENTIAL DIAGNOSIS—BENIGN AND MALIGNANT POLYPS

The differential diagnosis between benign and malignant polyps is, at times, extremely difficult. When these tumors are within reach of the examining finger the induration, fixation and firmness of malignancy is pathognomonic. The soft nonindurated mucosal polyps will rarely reveal any evidence of cancer. Usually, however, reliance must be placed on the pathologist for the differential diagnosis. Tissue should be removed from these tumors for histologic examination whenever they can be visualized. This can be done as an office procedure. One must realize, however, in doing this that there will occasionally be troublesome hemorrhage from such rectal biopsies. For accuracy in the differential diagnosis of malignant degeneration in these tumors it must be remembered that cancer can arise in any portion of a mucosal polyp. The entire polyp, together with its base, should be studied histologically before a final diagnosis of the nature of these tumors can be established.

Of late, increasing numbers of patients are being referred to us with a tumor of the rectum or sigmoid for whom a biopsy has been performed and a diagnosis of cancer established. A review of the microscopic slides of these specimens coming with the patients and repeated biopsies of these tumors have, many times, failed to confirm the diagnosis of cancer. We believe that there may be a tendency among pathologists not dealing with polyps in considerable numbers to diagnose some of these borderline lesions as malignant a little more often than seems justified.

The importance of the accuracy of the histologic diagnosis of these tumors (polyps) cannot be over-emphasized. To a large extent, the decision as to the type and extensiveness of radical surgical treatment which will follow is based on the interpretation of the microscopic observations by the pathologist. The diagnosis of tumors in many other parts of the body as malignant growths may be of relative unimportance by comparison, since the treatment of a precancerous lesion and of cancer may often be similar or identical. However, when dealing with epithelial tumors of the large bowel, overenthusiasm in the diagnosis of malignancy may be extremely serious, since, with rare exceptions, the diagnosis of cancer is the only diagnosis which necessitates a radical surgical removal, frequently with permanent colostomy.

The microscopic recognition of cancer in a biopsy specimen removed from the rectum is not difficult if the tumor is well developed. The tumor shows atypical cells, irregularity of glandular structure and invasion of adjacent structures. There are borderline lesions, however, in which the criteria may not be so definite. The differential diagnosis between the benign but actively growing polyp and carcinoma arising in a polyp frequently must be made. The criteria used in this clinic for the differentiation have previously been outlined by Swinton and Warren.⁴ The diagnosis is based primarily on anaplasia, irregularity of architecture and invasion, at least two of the factors being present for the diagnosis of malignancy. One exception is definite lymphatic or blood vessel invasion, which is usually sufficient in itself for the diagnosis.

Fig. 4.—Adenocarcinoma with blood vessel invasion, showing invasion of large vein near center of field and attachment of tumor to vein wall (Verhoeff stain X 50).

Additional criteria which should be emphasized in the diagnosis of malignant disease in this region are mentioned.

1. Cancer must not be diagnosed on the mere presence of numerous mitoses in the tumor. Benign polyps often show many mitoses.

4. Swinton, N. W., and Warren, S.: Polyps of the Colon and Rectum and Their Relation to Malignancy, *J. A. M. A.* 113:1927-1933 (Nov. 25) 1939.

2. The presence of epithelial cells within vessels often occurs as an artefact produced by cutting the tissue. For the diagnosis of cancer, the intravascular epithelial cells should at least be associated with a thrombus and preferably by actually invading the vessel wall (fig. 4).

3. All portions of the biopsy must be examined before a negative report is made. Otherwise, a small focus of malignant change may be overlooked.

4. The diagnosis of cancer should never be made on borderline evidence. The pathologist should not feel compelled to diagnose tissue which is inadequate. The clinician and pathologist must both appreciate that repeated biopsies may be necessary before a definite decision can be made.

ROENTGENOGRAPHIC EXAMINATION

When symptoms suggest the possibility of organic disease in the colon or when examinations, as already discussed, have not revealed the origin of rectal bleeding or other abnormalities of bowel function, further examinations must be made of that portion of the colon above the reach of the 10 inch (25 cm.) instrument. For this region reliance must be placed on the observations of the radiologist. Malignant disease found in this region will approximate 30 per cent of the cancer encountered in the colon and rectum.

Patients selected for radiologic study of the colon should be selected on an individual basis and only after a careful history has been taken and physical, digital and sigmoidoscopic examinations of the lower bowel have been performed. It must be remembered that radiologic studies are not only important from the

point of view of making an original diagnosis but also may be indicated to determine the presence of multiple lesions. In our experience, 42 per cent of the polyps found have been multiple. Thus, the multiplicity of both benign and malignant tumors should be considered.

When advanced or large tumors of the colon are present, the preparation of the colon before radiologic studies are made is probably not too important, but if early or small lesions are to be demonstrated, the colon must be free of fecal material. It is our policy to prepare the

Fig. 5.—History of increasing constipation with loss of weight and rectal bleeding. On proctoscopic examination a mass was demonstrated in the lower left quadrant of the abdomen. Results of sigmoidoscopic examination were negative. A barium sulfate enema without preparation showed a tumor of the ovary with small bowel obstruction.

colon for this purpose by giving $1\frac{1}{2}$ (44 cc.) to 2 ounces (59 cc.) of castor oil the night before examination. A vigorous cathartic should not be given when an acute inflammatory process, ulcerative colitis,

intestinal obstruction or appendicitis is suspected (fig. 5).

On the morning of the examination, a tap water or saline enema is given three hours before the barium sulfate enema. If sigmoidoscopic examinations are performed using this same preparation they should be

Fig. 6.—Colon polyp demonstrated by contrast air enema.

made two to three hours before the barium sulfate enema radiograph is made, to allow evacuation of air which usually enters the colon at the time of the sigmoidoscopic visualization.

The routine barium sulfate enema radiograph is performed at the clinic as follows: a solution is made of 1 cup (235 milliliters) of barium sulfate plus 2 teaspoonfuls (8 to 10 milliliters) of tannic acid to each quart (0.95 L.) of warm water. The barium solution is allowed to enter the bowel slowly, the patient turning from side to side after filling of the ampulla so that clear visualization of the sigmoid can be obtained, particularly of those blind loops which extend posteriorly. After complete filling and observation fluoroscopically, roentgenograms should be taken in the posteroanterior and oblique positions so as to demonstrate all coils of the sigmoid. When a search is made for a lesion at the ampulla, lateral views of the ampulla should also be taken. The patient is then allowed to evacuate the colon and the three roentgenograms of the colon are again taken.

After this examination, if there is still a question of a lesion, particularly a polyp, a double contrast air enema of the colon should be considered.

There has been a tendency, probably more among clinicians than radiologists, to overemphasize the value of the contrast air enema. For those lesions involving the bowel the usual barium sulfate enema radiograph

is usually adequate. There are certain lesions which do not involve the bowel musculature, but which arise from the mucosa and extend into the lumen of the bowel, such as polyps, which can be better demonstrated by the contrast air technic (fig. 6).

When contrast air studies of the colon are made, a preparation similar to that already mentioned should be given. It is our policy at the clinic to carry out this study at a separate examination using a second preparation. A small amount of barium sulfate, a mixture of 1 cup to a quart of water, is used and the ampulla and sigmoid filled under fluoroscopic control. The patient is then allowed to evacuate and the colon filled with air. This allows an adequate demonstration of the mucosal markings of the colon. Stereoscopic roentgenograms are necessary for the most accurate study. These are taken with the patient in the prone and slightly oblique positions to demonstrate the coils of the sigmoid in relief. Both roentgenograms are taken while the patient holds a single breath to avoid motion. Even with examinations of this type we have had difficulty in demonstrating small mucosal polyps above the reach of the 10 inch (25 cm.) instrument. It has been our policy when such polyps are encountered to repeat the radiologic studies after a short interval, identifying the tumor at a second examination in the same location as that discovered at the first before submitting the patient to operation.

Fig. 7.—Demonstration of mucosal pattern in the large bowel. The loss of pattern in the rectum with irregularity is due to a large carcinoma of the rectum.

The limitations of the radiologic investigations of the rectum and sigmoid colon must be thoroughly appreciated. For the purposes of this presentation 161 cases were reviewed in which a barium sulfate enema roentgenogram of the colon was performed after a careful

history, physical examination, digital examination of the anal canal and sigmoidoscopic examination of the rectum and lower sigmoid. The results of this study are shown in table 2.

This reveals that it is not possible at the present time with our present known radiologic technics to diagnose

Fig. 8.—Diverticulitis with large bowel obstruction simulating a malignant growth.

many of the lesions of the ampulla of the rectum, the rectosigmoid area and, in certain instances, in the distal part of the sigmoid (fig. 7). The diagnosis of lesions of the colon beyond the reach of the sigmoidoscope is considered accurate. The bowel is usually accurately

TABLE 2.—Results of Radiographic Studies of Colon and Rectum (Barium Sulfate Enema and Contrast Air Technics)

observed in roentgenograms both in the full and empty states, particularly in the empty in which the mucosal markings are well demonstrated. The use of tannic acid has improved our previous technics. It must be emphasized again, however, that even in this region of the bowel, radiologic studies are not perfect and no hesitation should be made in repeating such studies when the diagnosis is uncertain.

Retained barium in the colon may be a serious complication at the time of operation. When operation

is to be performed soon after the barium mixture has been introduced into the colon, cathartics and enemas may be necessary to remove such barium before the surgical procedure is undertaken.

Much has been said and written on the differential diagnosis of organic disease of the colon. In our experience, the most important problem has been the differential diagnosis between malignant disease and diverticulitis of the sigmoid. This is a problem which cannot be definitely settled by radiologic study alone in many instances. In this group of patients, the importance of the history and physical observations, the presence or absence of rectal bleeding and the sigmoidoscopic appearance of the bowel below the lesion may be helpful. There will be a group of cases, however, which will require actual surgical exploration before a definite diagnosis can be established.

Fig 9.—Large polyp of the sigmoid colon simulating a malignant growth.

From the radiologic point of view the presence of a "shelf" at the beginning and at the end of the filling defect is strong evidence of malignant degeneration. The fact that mucosal markings of the colon in the involved lesion are usually destroyed when carcinoma is present, whereas they remain intact in diverticulitis, has not been of much assistance to us. The lesions of diverticulitis usually involve a larger portion of the colon than does carcinoma, but this is not pathognomonic (fig. 8).

SURGICAL EXPLORATION

There will also be a few instances in which the differential diagnosis between benign and malignant polyps cannot be established without surgical intervention.

On exploration, the differential diagnosis between cancer and diverticulitis of the sigmoid frequently cannot be established on inspection and palpation of the lesion. In these instances it has been our policy to

carry out a local resection of the involved bowel and have an immediate histologic examination performed. The pathologic recognition of cancer of the colon when the entire specimen is thus submitted usually is not difficult. Further immediate surgical steps can then be planned accurately on the basis of this examination.

When a polyp is found in the lumen of the colon through a colotomy incision, in most instances a long pedicle of normal mucosa will be encountered. Local excision is adequate for tumors of this type even though ultimate histologic study may at times reveal areas of early malignant degeneration. Local resection of the bowel and tumor may be necessary before a final decision from the pathologist can be given as to the presence of malignant disease and the extent of resection indicated (fig. 9).

SUMMARY

The symptoms and methods of examination necessary for the diagnosis of cancer of the colon and rectum are reviewed. The necessity for the routine use of the sigmoidoscope in every physical examination of adult patients for the detection of premalignant lesions is emphasized. The criteria for the histologic diagnosis of malignant disease in this region are given. The tendency of many pathologists to "overdiagnose" borderline lesions of this type is mentioned. The indications for and the technic of radiographic studies of the colon are given. The limitations of the barium sulfate enema and contrast air technics of radiographic study of the colon and rectum in the diagnosis of cancer are discussed.

ABSTRACT OF DISCUSSION

DR. HARRY M. WEBER, Rochester, Minn.: It is most important to remember that the patient with cancer of the colon may exhibit one, several, all or none of the symptoms of the disease that have been listed. Certainly there is a stage in the development of neoplasm of any internal organ when there are no clinical manifestations whatever of its presence. Obviously, then, a patient exhibiting one or several of the symptoms mentioned should undergo all of the special examinations described and in the order in which they were listed: inspection and palpation of the external anal region, digital examination of the rectum, competent proctosigmoidoscopic examination and competent roentgenologic examination of the colon. All of these examinations are necessary, regardless of the diagnostic yield of any one of them. The large intestine is notorious for its capacity to develop multiple neoplastic lesions. Frequently, for instance, an adenomatous polyp of the rectum is accompanied, followed or preceded by carcinoma of more mature proportions at a more orad level in the colon. Dr. Swinton and his co-workers pointed out that there is no certain way of knowing that any intestinal polypoid lesion is not cancer short of microscopic examination, not only of a part of the lesion but of the entire lesion. For practical purposes there is no reliable gross pathologic diagnosis of benignancy, once the presence of neoplasm is established. Hence such a polypoid lesion must be extirpated in toto, if for no other reason than to become certain of its malignant or benign nature by careful histologic study. To keep such a lesion under observation in situ until it shows advancing growth, induration, extension or other more definite evidence of malignant neoplastic change is to gamble unnecessarily with the patient's longevity. It is not certain that all cancers of the large intestine begin as polypoid lesions, but it is certain that a great many of them do. Thus the early diagnosis of intestinal cancer, even of intestinal precancer, is an actual possibility in this

day, and this diagnosis consists in the recognition of the small polypoid lesion. If such a polypoid lesion proves to be an adenomatous polyp it may be cancer at the time, but, if it is not, it will almost surely be cancer some day if its bearer lives long enough. This fact makes the clinical management of such a lesion obvious. With proctosigmoidoscopy and the roentgenologic examination of the colon, both assumed to be competently performed, we have the means of detecting these lesions even earlier in their development than they will manifest themselves by clinical signs and symptoms.

DR. WILLIAM H. DANIEL, Los Angeles: Dr. Swinton and his co-workers have clearly outlined the essential points in the diagnosis of cancer of the colon. Any of the three cardinal symptoms, however slight, are danger signals and must be proved innocent or serious by the proper examinations. The proctologist begins his search at the anus and attempts to visualize the bowel surface through the sigmoidoscope to at least 8 (20 cm.) or 10 (25 cm.) inches, using intravenous anesthesia if necessary. The barium sulfate enema should follow, to rule out higher lesions. If one is suspected, especially when streaks of dark blood are a constant observation, the double contrast enema should be given and repeated, to definitely rule out or confirm the presence of a polyp or beginning cancer. Since benign and malignant polyps are often associated with advanced carcinoma, it is reasonable to assume that the cancerous lesion itself may have originated as adenoma or a polyp. It is my practice and that of my colleagues to utilize the double contrast enema in every case in which a polyp is demonstrated by the sigmoidoscope, because of the tendency to multiplicity of polypoid lesions. In approximately 17,000 private patients there were 811 malignant lesions (4.7 per cent), including 32 anal epitheliomas and 74 polyps and adenomas (0.421 per cent). In the same group there were 581 patients (3.3 per cent) with benign adenomas and polyps. The majority of the polypoid lesions were found on routine sigmoidoscopic examination. Sections from several areas of the polyp should be studied by the pathologist in order to determine the degree of malignancy if present. I agree with the authors that the difference between a benign and malignant lesion depends on the pathologist who reads the slide. This is important, especially in the large villous adenomas, for which radical operation may be performed with sacrifice of the rectum when local treatment by fulguration usually is sufficient. The differential diagnosis between cancer and diverticulitis is not always simple. The roentgen observations may not be typical. A cancer may perforate the bowel, causing a perisigmoiditis and proctitis. Surgical intervention is indicated when there is any doubt, and then it may be impossible to differentiate by palpation, especially when the cancer is surrounded by an inflammatory process.

DR. NEIL W. SWINTON, Boston: I did not intend to imply that we hold our radiologists responsible for the diagnosis of lesions in the lower 10 inches (25 cm.) of the bowel. I do not believe that we have a local situation entirely. A large number of our physicians who see patients with rectal bleeding, and do or do not carry out a digital examination, have a roentgenogram of the colon taken, using a barium sulfate enema, and then inform the patient that there is nothing seriously wrong. The patient must have a sigmoidoscopic examination, preferably before roentgenograms of the bowel are taken.

Medieval Football.—In his historical essay on Florentine football (*Calcio*), Count Giovanni Bardi, in 1688, described medieval football in detail. . . . To a certain extent, football in Italy succeeded and supplanted the tournaments. Thus a *Gala Calcio* was held generally on grand occasions such as the visit of a foreign potentate or an important marriage. Two of the most famous games were performed in February, 1530, despite the siege of Florence, and in the summer of 1558, on the occasion of the nuptials of Dona Leonora de' Medici . . . and Alphonse d'Este, son of the Duke of Ferrara.—Joseph, Ludwig H.: *Ciba Symposia*, March-April, 1949.

LABORATORY ASPECTS OF STREPTOMYCIN

EMIL BOGEN, M.D.
Olive View, Calif.

In the few years since streptomycin was discovered and made available, it has already become established as an important agent in the treatment of many diseases.¹ Much enthusiasm has been evoked by the demonstration of its effectiveness in many hitherto refractory tuberculous lesions. Extensive resources have been utilized in its investigation, and much has been learned about it, but much still remains to be investigated.

Numerous other antibiotics besides penicillin and streptomycin have appeared promising from in vitro tests, but proved to be too toxic or feeble in animal experimentation. A few are undergoing trial, but none yet available have warranted clinical recommendation for tuberculosis. Many chemical agents have been found tuberculostatic, or tuberculocidal in vitro; some have shown promise in animal experiments, and several, including promin® (sodium p,p'-diaminodiphenyl-sulfone-N,N'-dixetrose sulfonate), promizole® (4,2'-diamino-diphenyl-5'-thiazole sulfone) diasone® (disodium-formaldehyde-sulfoxylate-diamino-diphenyl-sulfone) and para-aminosalicylic acid, are being studied in patients, but none so far tested approach the effectiveness of streptomycin.

CHEMICAL STRUCTURE

The chemical structure of streptomycin as N-methyl-glucosamido-streptosido-streptidine has been confirmed. Several chemical variants, such as streptomycin B and dihydrostreptomycin, have been identified. Terminology may now be based chiefly on chemical identity, rather than on origin or properties, though synthesis still remains for the future. Newer preparations, such as the streptomycin calcium chloride complex and crystalline streptomycin, as well as the chloride and sulfate, are being produced in greater quantities, purer, more soluble and stable and less toxic than the crude materials available to the earlier workers. The lessened cost of streptomycin, with the lowering of the average daily dose and the shorter duration of the treatment, has greatly reduced the economic limitations to its use.

Colorimetric and fluorometric methods of chemical assay for streptomycin have been introduced, but simpler and more sensitive tests for the determination of streptomycin levels in blood or urine are wanted. The maltol test may have more general application in assays of concentrated preparations. Improved technics and greater experience with dilution, slide and plate methods of bioassay for streptomycin have increased confidence in their dependability. With the lower dosage now found effective, however, it appears unnecessary to perform the routine blood level studies earlier recommended.

ABSORPTION

The few reports of the rate of absorption of streptomycin from various channels in animals and human beings are based generally on earlier, less precise, bioassay technics. They show, in general, highest concen-

Read before the Section on Miscellaneous Topics at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 24, 1948.

trations immediately after intravenous, about one hour after intramuscular and still later after subcutaneous administration. The maximum blood level obtained after an injection approaches about twice the dose given divided by the body weight. Oral administration does not usually result in enough absorption to be shown by blood levels, though traces may be found in the urine. Absorption following inhalation into the lungs in the form of sprays or aerosols, or in micronized form, or following deposition in the upper respiratory passages, mouth or other sites has been reported with differing results. Few data are available regarding its absorption from the pleura or peritoneal cavities. Its absorption

into the blood stream from intramuscular injection cannot be controllably delayed by suspension in beeswax and oil, as with penicillin; but there is inadequate information regarding this or the effects of local cold applications or epinephrine and the like on absorption rate or on possible differences in the absorption rates of various compounds of streptomycin.

EXCRETION

Streptomycin is excreted, mainly in the urine, more slowly than is penicillin. It is eliminated chiefly by glomerular filtration. Carinamide or other substances which delay tubular excretion of penicillin do not, accordingly, have this effect on streptomycin. The effect of fluid restriction or other methods of lowering glomerular output appears slight. Streptomycin excreted in the urine may cause a weak reduction of ordinary sugar reagents, leading to reports of glycosuria. Other channels of excretion, such as the bile, feces and sputum, have been noted.

After the intramuscular injection of large amounts of streptomycin the concentration in the blood generally appears to be proportional to the amount given to any one animal. The rate of decline in this blood level does not appear to follow a straight line decrease, such as is seen with ethyl alcohol in the blood independent of concentration, but is closer to the logarithmic decline observed with penicillin or methyl alcohol, where the higher the blood level the greater is the amount excreted per time unit. After the injection of small amounts, streptomycin appears less regularly and disappears more rapidly from the blood stream. The rate of fall seems faster in dogs than in human beings. The concentration in the blood falls to one half of the previous level, in the average patient, in less than three hours, but may be greatly retarded in instances of renal retention.

DISTRIBUTION

Regarding the distribution of streptomycin throughout the bodies there are conflicting results based chiefly on studies in human beings and in a few cases on animal studies. It does not appear to diffuse through the tissue as readily as does penicillin, and there are differences in its final concentration in various organs. Thus, low levels have been noted in the spleen and liver and none in the brain. It appears to be distributed chiefly in the extracellular fluids, even that in the blood being found in the plasma rather than in the cells. More data are desired regarding the rate of distribution into various tissues and, also, the rate of return from these tissues back to the blood stream.

Trypan blue and certain other dyes show a selective predilection for the reticuloendothelial system and for lesions of tuberculosis. Streptomycin concentration in certain organs and lesions may be increased by coupling to the trypan dyes according to several studies. However, such increased concentration in the reticuloendothelial tissues or in the lesions do not appear to increase the therapeutic efficiency of the streptomycin.

TOXICITY

The toxicity of streptomycin has been found to be low for chick embryos, making possible the study of effects of streptomycin on mycobacteria, rickettsia and other organisms in such preparations, and the use of streptomycin to inhibit contaminations by susceptible organisms in the cultivation of resistant viruses, etc. Toxic effects have been noted with large doses in mice, rats, guinea pigs, rabbits, cats, dogs, monkeys and other animals. Most of our knowledge of the toxic properties of streptomycin, however, proceeds from the observations of treated patients.

Toxic manifestations may consist of allergic responses to pure streptomycin or to impurities in it. Sensitization may result from very small doses, by any route or even from casual contact by the nurse's handling of used syringes or in a neighboring patient exposed to escaping aerosol, with resulting dermatitis or other symptoms. Eosinophilia is frequent but unimportant. Acute histamine-like reactions early reported were probably due to impurities, but similar reactions may follow intravenous or even intramuscular injection in previously sensitized persons.

Local irritation seems chiefly due to impurities. It differs with various preparations of streptomycin and with different mode of administration. Simultaneous use of procaine hydrochloride is of little value in this connection. Renal irritation is common, but serious

renal damage leading to anuria appears to occur only with excessive dosage or with previous renal impairment leading to retention and high blood levels. Its danger is greatly reduced if not eliminated by the use of lower dosage. The hepatic and hemopoietic injuries encountered, though anticipated on the basis of animal experiments, have perhaps been coincidental, but must be seriously considered as they may otherwise be readily overlooked. Nutritional disturbances have been reported in animals as a result of elimination of vitamin forming intestinal bacteria by oral administration.

Complete and permanent loss of vestibular function develops in most patients receiving large doses for prolonged periods or who have excessive blood levels as a result of renal retention. With smaller, briefer or interrupted dosage the dysfunction may be only partial or temporary. With lower but still therapeutically active doses, vestibular damage may be completely averted. Experimentally similar disturbances have been observed in animals, especially the cat, and less readily in descending order in dogs, rabbits, rats and guinea pigs. Despite reports of degenerative changes in the vestibular nuclei, the exact nature and locus of the lesion involved is still obscure.

Deafness, though a distressing possibility, is so rare as to be practically negligible. The few cases reported have been generally among patients treated for tuberculosis meningitis, where the disease process, or the effects of the intrathecal injections, may be responsible. Local spinal cord or nerve injuries, including transverse myelitic syndromes, have resulted from intrathecal injection of large amounts or too concentrated or irritating preparations of streptomycin as well as from the trauma of frequent lumbar punctures. Paresthesias, especially of the face, are common, but fortunately mild and transitory. A few psychotic episodes have also been encountered. Other neurotoxic effects have been too rare or uncertain to establish etiologic relationship to the treatment.

Moderate but continuously sustained concentrations of streptomycin in the blood are more apt to be associated with toxic manifestations than are high peaks with intervening low levels. Toxicity may be reduced, therefore, by less frequent injections or by interrupted treatments. The clinical effectiveness of such dosage suggests that the therapeutic effect is not due to the same mechanism as that producing toxicity. Although antihistamine drugs may control some of the allergic manifestations of streptomycin sensitivity they do not seem to prevent vestibular damage. Desensitization by small doses has been reported as lessening vestibular damage, but this has not been confirmed.

MAXIMUM LIMITS

Deaths due to streptomycin have been observed in various species. The lethal component of commercial streptomycin has not been identified, and the mechanism of death in animals succumbing to it is still obscure. The earlier crude preparations of streptomycin killed animals in much smaller doses than do the purer products now available. There is also some variation in the toxicity of different lots of the same form. Nevertheless, much has been learned regarding lethal dose limits. Large animals withstand larger amounts than small ones. If the dose given is directly proportional to the body weight, however, large animals may be affected more than are small ones. If the effective dose depends on the total body fluids or of

the blood volume rather than of the body weight, it would be more nearly proportional to the two-thirds or three-fourths power of the weight than to the weight itself. Blood levels after known doses of streptomycin on animals of different size tend generally to confirm these conclusions. Blood levels of 500 micrograms per milliliter or more are found in the blood taken after death in experimental animals.

Clinically vestibular toxicity has also been more pronounced in small patients when a uniform dose has been given to all, but it has been more pronounced in large men when the dose given is in proportion to the body weight. On the basis of animal experiments less than 20 Gm. of streptomycin sulfate or about 400 micrograms per kilogram of body weight injected intramuscularly at one dose may be expected to kill the average human being. Much less than this might be fatal to sensitive persons or with more toxic preparations. Actually as much as 3 Gm. of streptomycin has been given patients at a single time, and this amount in divided doses during each day has been taken by many patients for several months without a fatality.

THERAPEUTIC DOSAGE

Studies, both in experimental animals and in patients, have yielded extensive data regarding minimal, maximal and optimal therapeutic daily dosage and individual dose and frequency of administration. The administration of about 2.0 mg. per kilogram of body weight or 0.1 Gm. in an average man, giving peak blood levels of about 4 micrograms per milliliter, appears to be the lowest daily dosage which will affect tuberculosis. Better results are obtained up to about five times these figures, at 10 mg. per kilogram of body weight or about 0.5 Gm. per day in human beings, giving blood levels of about 20 micrograms per milliliter. Increasing the dosage above these figures gives little improvement in results.

The streptomycin therapeutic effect on the tubercle bacillus, at least, is exerted by high peaks with intervening low blood levels, as well as by moderately low but continuous blood level with persistent exposure of organisms to its action according to both animal and clinical observations. Recent reports suggest that the same may be true of penicillin, despite previous beliefs.

ANTAGONISTS

No specific antagonist to streptomycin, similar to the para-aminobenzoic acid-neutralizing sulfonamide drugs, or the penicillinase-inactivating penicillin, has been established. Lipositol, extracted from brain tissue and soy bean lipids, hydroxylamine, semicarbazide, cysteine, ascorbic acid, 2,3-dimercaptopropanol (BAL) and other reducing agents have been reported to interfere with streptomycin, but the mechanisms involved need further study. Salts, sugars, serum, peptones, tweens® (a series of polyoxyalkylene derivatives of hexitol anhydride partial long chain fatty acid esters) and other constituents of the culture medium have also affected its activity in the hands of some workers, but not under other conditions. Increase in the activity of streptomycin as a result of the presence of enhancing factors has also been described.

BACTERIOSTATIC ACTION

Though all agree that streptomycin inhibits most tubercle bacilli *in vitro*, some observations suggest that streptomycin interferes with multiplication of tubercle

bacilli rather than with oxidation, growth or metabolic functions. Thus, tubercle bacilli inhibited by streptomycin have appeared larger and coarser or older than the same organisms growing in the absence of streptomycin. The tellurite test indicates that enzymatic processes continue in tubercle bacilli the multiplication of which has been inhibited by the presence of the antibiotic. Other studies of oxidative and other reactions have been made. Reports of bactericidal effects on stable cultures of tubercle bacilli or only on young growing cultures of these organisms, by several workers, have not been confirmed by others or in our laboratory (Western Trudeau Streptomycin Laboratory).

Delayed appearance of growth may be accounted for by complete inhibition of a fraction of the total organisms present rather than by partial inhibition of the entire culture. This is shown by a prolongation of the latent period before visible growth is noted, after which logarithmic growth curves manifest similar slopes. A variable latent period in the effectiveness of the antibiotic, that is, persistence of growth for a short period after the antibiotic has been added to a culture, especially with low concentrations of the antibiotic and large numbers of organisms, has been observed, though this seems to be absent when great excess of the antibiotic is present. On the other hand, despite clinical indications of prolonged effect, especially in animal experiments, *in vitro* observations fail to confirm the existence of a delayed persistent effect after the antibiotic has been completely removed from the culture medium.

STREPTOMYCIN RESISTANCE

The existence of streptomycin-resistant forms of acid-fast bacilli as of other organisms has been established. Repeated transplantation from subeffective concentrations of streptomycin in culture mediums has been used in order to obtain resistant forms, but, if heavy inoculations are made, gradual increase in concentration is unnecessary. Resistant tubercle bacilli have been rarely found in untreated patients. The general frequency of resistant forms in treated patients and their range and persistence has been confirmed. Discrepancies in the results with different methods of determining resistance have been reported. New mediums and culture methods are being developed which may facilitate the quantitative determination of resistant forms. Organisms resistant *in vitro* are also resistant to treatment in experimental animals and probably in patients.

Differences in the morphologic aspects, physiologic behavior, growth rate or virulence in the tubercle bacillus following the development of resistance have been reported, but my co-workers and I have not been able to confirm these observations at Olive View. Resistant forms may appear to differ morphologically from sensitive ones in the presence of streptomycin, since the resistant ones continued to multiply and so may show a greater variety of size and shapes, but when streptomycin is not present such difference may not be seen.

Stimulation of growth of susceptible organisms by concentrations too low to be bacteriostatic, or "hormesis," and the stimulation by, or even complete dependence of, resistant organisms on the antibiotic, such as has been reported for meningococci and other organisms, has also been reported with virulent tubercle bacillus, as well as with a related form. The progression

of tuberculosis in patients after their organisms have become resistant has been interpreted by some workers as representing such "hormesis" *in vivo*.

Resistant forms sometimes develop in mediums containing high concentrations of streptomycin, while other cultures inoculated at the same time with lower concentrations have failed to show any growth at all. The occurrence of these "skips," "saltations," "paradoxical zones" or "inversions" suggests that the appearance of resistant forms is a chance phenomenon, revealed in large numbers of organisms by the inhibition of more susceptible ones but otherwise independent of the presence of streptomycin in the medium. Clinically, also, resistant forms cannot be prevented or delayed by heavy continuous treatment and do not appear earlier or more frequently with little or intermittent treatment.

COMBINED TREATMENTS

In the test tube, as well as in experimental animals, sulfones and other agents which have a weak anti-tuberculous activity seem to combine with streptomycin to inhibit the growth of the organisms. Whether this is a true potentiation or synergism with increasing effect on combination or whether it is a mere additive or even partially additive effective is difficult to demonstrate. Sputum conversion or the disappearance of tubercle bacilli during streptomycin treatment is evidence of their susceptibility. When streptomycin treatment is combined with collapse therapy or other measures to control disease and stop the multiplication of the organisms, such sputum conversion occurs more frequently than when streptomycin alone is relied on. Patients now receiving treatment with combinations of streptomycin with collapse therapy, sulfones or other agents are being studied to see if they may be of clinical importance in delaying or preventing the appearance of resistant forms.

PATHOLOGIC STUDIES

Histologic examination of lesions which have responded to streptomycin treatment, both in animals and in human beings, shows pictures of regression, encapsulation and resorption or of persistence and progression similar to, though more frequent than, that encountered without streptomycin treatment. Most animal experiments have been performed with primary tuberculous infection, while most patients have been treated for lesions of the reinfection type. Results in a few animal experiments and a few children with primary infection who have been treated indicate, however, that the streptomycin is similarly effective in both forms.

Further experience has confirmed the emphasis on the location and age of the lesion rather than on immunologic character. Active tuberculous ulceration and granulations of the mucous membranes and draining sinuses from tuberculous lymph nodes or bones and joints have given the most strikingly uniform response. Recent acute miliary disseminations may fade away and tuberculous meningitis may show prolonged remissions, but recurrence or relapse and eventual failure are only too frequent. Fresh pulmonary exudates absorb rapidly and caseation encapsulates and shrinks, in experimental animals and in human beings, but the effects are too often incomplete. The lesions may recur or progress when the treatment is discontinued or the organisms become resistant. Fibrosis and cavitation resulting from destruction and replacement of pulmonary tissue are only symptomatically affected by the

treatment. The same is often true of renal and genital tuberculosis. Fistulas from tuberculosis of closed cavities in the body, as pleurocutaneous or bronchopleural fistulas in empyema, have also given disappointing results. With greater experience, physicians have become more conservative in assuming that a symptomatic response or apparent radiologic improvement will persist and have become more anxious to supplement streptomycin treatment by further surgical or chemotherapeutic measures.

SUMMARY

During the past year there has become available cheaper, purer and less toxic streptomycin, but it remains the only antibiotic of proved value in the treatment of tuberculosis. Its chemical identity has been established and chemical as well as biologic assay methods developed, but it has not yet been synthesized. It is absorbed only by parenteral routes, widely but not uniformly distributed in the body and excreted in the urine in a different manner than is penicillin. It appears to prevent multiplication without interfering with several other physiologic functions of tubercle bacilli, but the exact mechanism of its action is still obscure.

The blood levels after varying doses in different species of animals and in persons of different size have been studied. The minimal lethal doses and the toxic consequences of various doses and blood levels have revealed the limits of allowable dosage. Animal experiments and clinical experience have established the minimal effective daily dose that may be given. Smaller amounts given at greater intervals are safer and just as therapeutically valuable as the large amounts divided into frequent doses previously recommended.

Resistant forms of tubercle bacilli form the chief obstacle to its success. Combination of streptomycin with other forms of treatment, medical and surgical, offers at present the best hope of preventing the multiplication of these resistant forms. Indications for streptomycin have become more definite and its limitations are better appreciated, but much remains to be learned in order to utilize to the utmost this important advance in the treatment of tuberculosis.

ABSTRACT OF DISCUSSION

DR. ALLAN HURST, Denver: I would like to know whether Dr. Bogen has had any experience with the combination of streptomycin and promizole® (4,2'-diamino-diphenyl-5'-thiazole sulfone) as reported by Dr. Edith Lincoln. At the National Jewish Hospital, there is a patient who was treated at Bellevue Hospital and later reported as part of a series in the *Bulletin of the Johns Hopkins Hospital*. This girl of 15, with generalized tuberculosis, was reported successfully treated by a combination of promizole® and streptomycin. Since transfer to our institution evidence of renal tuberculosis has developed, with destructive changes in both kidneys, as well as joint manifestations. Treatment with promizole® is being continued at the request of Dr. Lincoln, but evidence has not been found that promizole® alone or in combination with streptomycin, has been of any real value in this case.

DR. EMIL BOGEN: My only experience with promizole® has been limited to a few tests and experiments and a single patient. My co-workers and I have had somewhat more experimental experience with diasone®, and recently rather considerably with promin® (sodium p,p'-diaminodiphenyl sulfone-N,N'-didextrose sulfonate) and similar diphenylsulfone agents. In the guinea pig, one can show slight retarding effects on tuberculosis from any of these agents; but none of them show anything comparable to the retardation shown by streptomycin alone.

There does seem to be some increase in the effectiveness of streptomycin when it is combined with a diaminodiphenyl-sulfone agent. In renal involvement, we have had some rabbit experiments in which the combination seems much more effective on the inhibition of renal lesions, particularly when we had added promin® intravenously, which is rather rapidly excreted. We obtain rather high concentrations of this in the urine, sufficient to cause inhibition of tubercle bacilli, and this treatment, combined with streptomycin or given to patients who have already had organisms resistant to streptomycin after previous treatment for renal tuberculosis, has shown gratifying clinical results. In renal tuberculosis, particularly, in spite of the impressive results shown in the exhibit of the New York work of the Veterans Administration, our own experience has been that organisms are apt to recur following a period of treatment, and we feel that combined treatment in this particular instance is indicated.

CONSTRICTION OF THE INTERVERTEBRAL FORAMEN

A Cause of Nerve Root Pressure

LEE A. HADLEY, M.D.
Syracuse, N. Y.

The intervertebral foramen, exit of the nerve root from the spinal canal, is limited in front by the intervertebral disk and portions of the adjacent vertebral bodies. Above and below are the pedicles, while posteriorly occur the superior and inferior articular processes, with the ligamentum flavum. This opening, which is the site of movement, is normally five or six times as large as the diameter of the nerve which passes through it, thus allowing a generous reserve cushion space. Nerve foramina, not the site of movement, are only slightly larger than the nerves which traverse

Fig. 1.—Roentgenograms of a portion of the spine of a stenographer, age 18. She had lifted a typewriter down from a high shelf and had experienced sudden pain down left leg. The transverse lines indicate the planes of the disk surfaces and relative sizes of the foramina (interpedunculate distances). A, bending to the left (painful side), the fourth lumbar foramen was maintained as large as possible. B, attempting to stand upright, with listing of the lumbar part of the spine away from the painful side. C, bending away from painful side, normal flexion. The disks are wedge shaped, thinner on the concave side. The diagnosis of fourth lumbar disk herniation was confirmed by operation.

them. In the spine this is noted in those cases of nonsegmentation in which adjacent vertebral segments remain congenitally fused. Here the foramen is much smaller, smooth in margin and usually round or slightly oval in shape.

Certain movements of the cervical and lumbar parts of the spine cause normal physiologic constriction of the foramen diameter. Dorsal extension and lateral flexion may decrease the diameter by as much as one third. In the cervical region, constriction also

Read before the Section on Radiology at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 23, 1948.
The Department of Anatomy and the Department of Pathology of the College of Medicine, Syracuse University, assisted in this study.

results from rotation. These facts may prove useful in eliciting or evaluating the patient's symptoms.

A radiograph of the lumbar part of the spine made with the patient standing at the full limit of lateral flexion will normally show the intervertebral disks wedge shaped, the narrow edge toward the concavity of the curve. In this anteroposterior view, the distance between the pedicles will be noted materially decreased on the side toward which the patient is bending.

In certain patients with symptoms of nerve root pressure, the upper and lower plane surfaces of the corresponding disk remain parallel. The foramen is not allowed to become smaller on lateral flexion toward the affected side, although normal wedging may take place at this level when the patient bends in the opposite direction (fig. 1). The adjacent disks may show normal wedging in both directions. Patients with limitation of movement from painful back conditions exhibit a more generalized restriction and absence of wedging.

In addition to the physiologic foramen constriction just described, encroachment on these openings may result from trauma, either fracture or dislocation.

So-called osteoarthritis is responsible for many cases of intervertebral foramen encroachment with consequent restriction of the reserve cushion space. This condition is not true arthritis but rather a noninflammatory degenerative process, more properly termed arthrosis or spondylosis. With this degeneration, thin-

Bony spur formation projects backward from the disk in front, or spur formation may project forward from the margin of the posterior articulation. The foramen becomes hour glass shaped.

Because of an incline to the plane of the posterior articulation, when the disk becomes thinned, the lower vertebra may become wedged forward—a reverse

Fig. 3.—Spondylolisthesis; the fourth lumbar disk is forward on the fifth. Disk substance is bulging into the foramen, and the nerve is flattened into a thin ribbon-like structure.

Fig. 2.—Serial sections of a normal fifth lumbar disk, foramen and posterior articulation. The top is medial, the bottom is lateral.

ning of the disk results, sclerosis of the vertebral body margins develops and the vertebral bodies come to lie more closely in contact. This approximates the pedicles decreasing the cephalocaudal diameter of the foramen.

spondylolisthesis—decreasing the anteroposterior diameter of the foramen. Along with this subluxation, the upper tip of the lower articular process becomes thrust forward into the opening (fig. 4).

There may be hyperplasia or ossification of the ligamentum flavum.

Examination of the lumbar region in cadaver material has frequently shown a bulging of disk substance backward and laterally into the foramen, especially at the levels of the fourth and fifth lumbar segments. This may occur well out in the lateral portion of the opening. At this level the disk forms the lower anterior border of the foramen, so that bulging of disk substance displaces the nerve upward and backward against the unyielding uppermost pedicle. The nerve structure may become compressed, so that its normal oval shape is flattened or altered to the shape of a triangle (fig. 5), and fibrotic changes with adhesions may develop in and about the nerve where it passes through the foramen. In these circumstances, the usual relationship between the size of the nerve and the diameter of a movable opening through which it passes is no longer the normal of about 1 to 5 and the cushion space is lost.

It would seem from these cadaver studies that changes within the intervertebral foramen may frequently occur which are compatible with the clinical picture of nerve root pressure.

"Herniation of the intervertebral disk" has unfortunately come to be a popular diagnosis applied to the condition in patients with symptoms of nerve root pressure. Although the pressure may be at any point along the root, it is usually sought in the spinal canal, too often without success.

Williams and Yglesias¹ in 1933 advised "facetec-tomy" to enlarge the intervertebral foramen in patients with intractable sciatica. Gray² of London, after reporting 2 cases in which there were symptoms of nerve root pressure cured by posterior joint arthrec-tomy where no disk protrusion was found, remarked, "Evidently the intervertebral disc is not the only factor." This author, in treating 298 patients with sciatica, operated on 55 by arthrectomy for arthritis of the posterior joint. Twenty-five were cured. In this country, Briggs³ has used arthrectomy to "decom-press" the intervertebral foramen. The cadaver studies here reported would seem to confirm the logic of such an operation.

Gray, in reporting on the postoperative roentgeno-grams of 17 patients who had had disks removed, found narrowing of one or more disks; this had not been visualized in the preoperative roentgenograms in 10 of them. Thus resulted a late posterior joint sub-luxation and presumably foramen encroachment. He warned against curettage of the disk during operation for this reason, stating, "Only the part that is loose should be removed, and no more."

Certain authorities now condemn the use of contrast myelography as being unreliable and have stated that the neurologist should be able to diagnose nerve root pressure by his clinical examination without it. Radio-graphs in the standing-lateral-bending position, as well as careful roentgen studies of the foramina, should be of some assistance. If nerve root pressure occurs in the intervertebral foramen, it can hardly be visualized by contrast medium within the dural sheath, nor can it be cured by operation solely within the spinal canal.

resistant cases may require operation. If operative intervention becomes necessary, not only the roomy spinal canal but the much smaller movable foramen must be investigated. This investigation must extend well out to the lateral side of the foramen structure. Decompression of the intervertebral foramen may be necessary.

Fig. 5.—Herniation of disk substance (1) into the intervertebral foramen compressing the fifth nerve root into triangular shape (2).

It would seem that these openings at the "cross-roads" between the peripheral nervous system and the movable skeletal support merit much greater attention than they have received in the past.

ABSTRACT OF DISCUSSION

DR. L. H. GARLAND, San Francisco: The author's thesis bears the respectability of years, as well as the hearty concurrence of spinal manipulators at large—but I am not sure that either proves it. In his belief that foraminate changes are an established factor in many conditions diagnosed as nerve root pressure, Dr. Hadley makes several statements which bear review: (1) That the intervertebral foramen is normally five times the diameter of the corresponding nerve. Anatomically this applies only in the upper cervical and in the thoracic areas. In the lower cervical and the lumbar areas the nerves virtually fill their respective foramina, at least in most adult spines. (2) That degenerative spinal bone changes (arthrosis and spondylosis are bad terms) are often associated with intervertebral disk narrowing and subluxations of the posterior spinal articulations, with resultant nerve pressure. Clinically one sees many persons with hypertrophic spinal changes (including posterior osteophytes in the lower cervical area), thinned disks and articular offsets—and absolutely no symptoms. Therefore, it is difficult to believe that significant nerve pressure often results from such. (3) That reverse spondylolisthesis is an entity which may result in "thrusting forward an articular process into the foramen." This, I believe, is a *rara avis*—if existent at all. There is considerable trouble in assessing the relationship of the various posterior articular processes and the relative sizes of the intervertebral foramina in living persons. Roentgenograms (stereo-oblique) are simple to make but difficult to duplicate. Slight differences in positioning and in the projection of the central ray may cause decided variation in the roentgen shadows of these structures. "Reverse" olisthesis is often an illusion, produced by variation in contour of the posterior margins of adjacent vertebral bodies. Apparent sub-

Fig. 4.—(1) A thinning fifth lumbar disk with reverse spondylolisthesis; (2) bulging of the disk substance into canal; (3) nerve root section; (4) subluxated articular process, encroaching on the foramen and impinging against the pedicle (5); posterior articular processes (6) do not register opposite each other. Perineural cushion space is almost completely absent.

Some patients will be relieved by rest alone, others by radiation applied to the nerve roots, while the most

luxations of articular facets (zygapophyseal joints) may also be secondary to positioning or technic. Both conditions (reverse slip and subluxation) do occur, but infrequently, and narrowed disks are not necessarily concomitant. Conversely, narrowed disks may be seen without grossly displaced facets, or evident foraminate narrowing. Therefore, I wonder whether the symptoms of nerve root pressure are not more likely to be due to soft tissue changes (degenerative, traumatic, etc.), rather than to alterations of foraminate shape or size. In either event, I believe that etiologic conclusions from roentgen studies are not always tenable. I would like to ask the author a few questions: (1) How many cadavers have been sectioned in these studies? (2) What percentage of compressed nerves secondary to articular subluxations were found? (3) Did review of the symptoms indicate good correlation?

DR. HENRY BRIGGS, East Orange, N. Y.: From operating and widely exposing foramina in over 100 patients and making explorations in many more, I am convinced that foraminate constriction is a common cause of back disability. Except in early stages, following a nuclear protrusion, foraminate constriction practically always follows some collapse of the intervertebral space. In teen ages the compression probably occurs after rupture of nuclear material into a vertebral body. As the bodies approximate, the disk bulges like a collapsing bellows and the ligamentum flavum thickens and bulges also. The disk bulge always carries out into the foramina in this group. In adults, after simple degeneration or degeneration with herniation, the same compression of the intervertebral space occurs and all the multiple manifestations described by Dr. Hadley follow. I have found all of them at operation, even a constriction that caused recurrent severe sciatica occurring seven years after a ruptured nucleus had been removed at the same level. The two common conditions that baffle me in operations on the low part of the back are the sucked back protrusions, called concealed disks, and the foraminate root oppressions. To determine the presence or absence of the first I have been in the habit of scraping the disk clean for inspection and palpation. To determine the latter adequately, part of the anterior surface of the inferior pedicle has to be removed by what I call an undermining foraminotomy. I am beginning to find evidence now that some of my explorations are followed by a late disk collapse. I wonder whether it is safe thoroughly to explore two and three disks in a search for pathologic changes. I find myself turning to the use of ethyl iodophenylundecylate (pantopaque®). As Dr. Hadley has pointed out, no contrast studies will solve the foraminate problem entirely, particularly at the lumbosacral level. Some of my best results have been in spines showing decided so-called hypertrophic arthritis, in which I have performed a wide opening of one or more foramina by adding to an arthrectomy a removal of part of the pedicles to their bases, doing what I call a complete foraminotomy. My guide for these operations has been disk collapse as shown on the lateral roentgenograms.

DR. LEE A. HADLEY, Syracuse, N. Y.: I wish to thank the men who have discussed my paper. Relative to Dr. Garland's question, I have been interested in studying the cadaver spines for the past eighteen years. I am sorry to have given Dr. Garland the idea that I feel that the spur, by itself, causes symptoms. Of course, one must differentiate between a harmless spur that projects laterally from the vertebral body and one that projects backward into the foramen. Many patients with spurs projecting into the foramen do not have symptoms. That condition, however, decreases or eliminates the normal protective reserve cushion space around the nerve. When the patient with such a condition inadvertently steps off a curb or gets a "snap the whip" effect to his neck from an automobile collision, he is likely to have nerve root pressure symptoms. Charles Gray, in *Surgery, Gynecology and Obstetrics* for November 1947, published an excellent article on this subject. It bears out some of the conclusions which I have enumerated, although his point of view was that of the surgeon. One cannot disregard the fact that in many cadavers, the nerve root is found to be definitely compressed into an abnormal shape by the surrounding structures.

Clinical Notes, Suggestions and New Instruments

AN EARLY SIGN OF FEMORAL THROMBOSIS

GERALD H. PRATT, M.D.
New York

The early diagnosis of thrombosis of the deep veins of the legs is one of the most difficult, as well as most important diagnoses doctors have to make. The condition, frequently, is unsuspected until embolism occurs. This missed diagnosis may cause a serious or a fatal complication. While surgical or anticoagulant therapy, or a combination of the two, can reduce effectively these complications, the diagnosis must be made first.

In a previous report on the diagnosis and treatment of thrombosis of the deep veins of the leg, I briefly mentioned the presence of three dilated veins over the tibia as an early sign.¹ Since then, this phenomenon has been observed so consistently that the term "sentinal" veins has been coined for it. I believe that these veins are the earliest objective sign of deep vein thrombosis and that attention should be directed to their presence so that effective therapy can be started. I have observed this sign early in over 80 per cent of the patients with pathologic clotting.

"Sentinal" veins. Dilated veins over the tibia, an early sign of thrombosis. In the illustration on the right, the process on the right leg preceded that on the left by two days.

It has been proved that the thrombosis which causes pulmonary embolism originates in most instances in the veins of the calf (Roessle,² Frykholm³ and Neumann⁴). This pathologic clotting results from a combination of factors, of which three are fundamental and constantly present. These three are: (1) an abnormal change in the blood clotting factor in the patient, (2) stasis of the blood flow and (3) endothelial irritation or injury.

The stasis and endothelial irritation may result from the trauma on the veins from bed rest alone. The clotting and thrombosis begin in the veins of the calf muscles and progresses to the popliteal vein. It propagates along the lining of the vein wall before occluding it. The first veins to dilate due to this obstruction are the ones opening directly into the popliteal vein, particularly branches of the anterior tibial vein. The collateral vessels are sufficiently abundant so that dilatation of the main veins with edema occurs very late, actually when the clotting has progressed to completely occlude the popliteal vein lumen. At such time, either embolism occurs or the obstruction is complete and edema results. These three small veins over

2. Roessle, R.: *Virchows Arch. f. path. Anat.* 300:180, 1937.

3. Frykholm, R.: *Surg., Gynec. & Obst.* 71:307, 1940.

4. Neumann, R.: *Virchows Arch. f. path. Anat.* 301:708, 1938.

the tibia empty into the saphenous and the anterior tibial vein system, are superficial and unsupported by musculature and therefore dilate very early.

This sign was present 84 times in 109 instances of thrombosis and lead to the early diagnosis. It is an earlier sign than the so-called Homans' sign. It is caused only by thrombosis, while the Homans sign may be positive in the presence of any inflammation of the skin or soft tissues in addition to a thrombosis.

This sign joins the other early diagnostic points which I have reported after studying 90 cases of fatal embolism and several hundred of nonfatal thrombosis.⁶ These signs are: (1) pain in the popliteal space or calf, (2) tenderness over the involved vein areas, (3) slight cyanosis of the part compared to the other one, (4) abnormally elevated pulse rate and temperature, (5) fear of impending disaster (many patients are aware that something is wrong), (6) very mild edema, (7) a small nonfatal embolism (25 per cent of the patients have a small embolism before a fatal one) and (8) "sentinal" veins as described.

Since most of these signs are subjective, an objective sign will be helpful in earlier diagnosis and treatment of this increasingly important syndrome.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., Secretary.

METHENAMINE-U. S. P. (See New and Nonofficial Remedies 1948, p. 122).

The following dosage form has been accepted:

THE WARREN-TEED PRODUCTS COMPANY, COLUMBUS 8, OHIO

Tablets Methenamine: 0.3 Gm. and 0.5 Gm.

METHADONE HYDROCHLORIDE (See New and Nonofficial Remedies 1948, p. 25).

The following additional dosage form has been accepted:

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Syrup Methadone Hydrochloride: 1.25 mg. per 4 cc., 473 cc. and 378 liter bottles.

METHIONINE (See THE JOURNAL, Oct. 9, 1948, p. 430).

The following dosage form has been accepted:

WALKER VITAMIN PRODUCTS, INC., MOUNT VERNON, N. Y.
Capsules Methionine: 500 mg.

GOLD AND SODIUM THIOSULFATE-N. F. (See New and Nonofficial Remedies 1948, p. 524).

The following dosage form has been accepted:

E. S. MILLER LABORATORIES, INC., LOS ANGELES 14

Solution Gold Sodium Thiosulfate: 25 mg. and 50 mg. Flacons.

OXIDIZED CELLULOSE (See New and Nonofficial Remedies 1948, p. 432).

The following additional dosage form has been accepted:

JOHNSON & JOHNSON, NEW BRUNSWICK, N. J.

Hemo-Pak Absorbable Gauze Packing Strip (4 ply): ½" x 5" (1.27 by 12.70 cm.) in sealed tube.

U. S. patents 1,939,235 and 2,232,990.

Council on Foods and Nutrition

The following water-packed fruits have been accepted as conforming to the Rules of the Council.

JAMES R. WILSON, M.D., Secretary.

The Pratt-Low Preserving Company, Santa Clara, Calif.

PRATTLow BRAND YELLOW CLING PEACHES consists of the fruit itself, packed in water without any added sugar or salt.

Analysis (submitted by manufacturer).—Moisture 91.9 per cent, ash 0.3 per cent, fat (ether extract) 0.1 per cent, protein (N X 6.25) 0.4 per cent, crude fiber 0.3 per cent, carbohydrates (by difference) 7.0 per cent, ascorbic acid 3.9 mg. per hundred grams.

Calories.—0.31 per gram; 8.8 per ounce.

Use.—For use in diets of patients on restricted sugar intake.

PRATTLow BRAND BARTLETT PEARS consists of the fruit itself, packed in water without any added sugar or salt.

Analysis (submitted by manufacturer).—Moisture 91.1 per cent, ash 0.2 per cent, fat (ether extract) 0.1 per cent, protein (N X 6.25) 0.2 per cent, crude fiber 0.6 per cent, carbohydrates (by difference) 7.8 per cent, ascorbic acid 1.5 mg. per hundred grams.

Calories.—0.33 per gram; 9.4 per ounce.

Use.—For use in diets of patients on restricted sugar intake.

PRATTLow BRAND UNPEELED APRICOT HALVES consists of the fruit itself, packed in water without any added sugar or salt.

Analysis (submitted by manufacturer).—Moisture 91.8 per cent, ash 0.4 per cent, fat (ether extract) 0.1 per cent, protein (N X 6.25) 0.5 per cent, crude fiber 0.3 per cent, carbohydrates (by difference) 6.9 per cent, ascorbic acid 3.9 mg. per hundred grams.

Calories.—0.31 per gram; 8.8 per ounce.

Use.—For use in diets of patients on restricted sugar intake.

PRATTLow BRAND FRUIT COCKTAIL, consisting for the most part of pears, peaches and pineapple with some grapes and maraschino type cherries, is packed in water without any added sugar or salt.

Analysis (submitted by manufacturer).—Moisture 89.0 per cent, ash 0.3 per cent, fat (ether extract) 0.1 per cent, protein (N X 6.25) 0.4 per cent, crude fiber 0.4 per cent, carbohydrates (by difference) 9.8 per cent.

Calories.—0.42 per gram; 11.9 per ounce.

Use.—For use in diets of patients on restricted sugar intake.

PRATTLow BRAND KADOTA FIGS consists of the fruit itself, packed in water without any added sugar or salt.

Analysis (submitted by manufacturer).—Moisture 87.4 per cent, ash 0.4 per cent, fat (ether extract) 0.1 per cent, protein (N X 6.25) 0.5 per cent, crude fiber 0.8 per cent, carbohydrates (by difference) 10.8 per cent.

Calories.—0.46 per gram; 13.0 per ounce.

Use.—For use in diets of patients on restricted sugar intake.

The following products have been accepted as conforming to the Rules of the Council.

JAMES R. WILSON, M.D., Secretary.

Maple Island Farm, Inc., Stillwater, Minn.

MIF INFANT FOOD consists of fresh, clean pasteurized milk, corn syrup solids, ferrous gluconate, vitamin A, vitamin D, thiamine hydrochloride, niacinamide and ascorbic acid.

Analysis (submitted by manufacturer).—Milk fat 21.0 per cent, milk proteins (N X 6.38) 23.0 per cent, lactose 32.0 per cent, dextrins, glucose and maltose, 17.0 per cent, ash, 5.0 per cent, moisture 2.0 per cent.

Calories.—4.75 per gram; 135.00 per ounce.

Vitamins and Minerals.—

	Per Hundred Grams
Vitamin A	2,600.00 U.S.P. units
Vitamin D	700.00 U.S.P. units
Thiamine Hydrochloride	0.65 mg.
Riboflavin	1.00 mg.
Niacinamide	6.50 mg.
Ascorbic acid	26.00 mg.
Calcium	750.00 mg.
Phosphorus	500.00 mg.
Iron	5.00 mg.

Use.—For infant feeding.

The Lynne Corporation, Oakland, Calif.

LYNNE BRAND DEHYDRATED GOAT'S MILK, a spray-dried, homogenized whole goat's milk.

Analysis (submitted by manufacturer).—Water 2.0 per cent, total solids 98.0 per cent, ash 6.5 per cent, fat 27.0 per cent, protein (N X 6.38) 26.5 per cent, lactose (by difference) 38.0 per cent.

Calories.—5.0 per gram; 142.0 per ounce.

Use.—As a replacement for cow's milk in special diets.

SATURDAY, JUNE 4, 1949

THE GROWTH OF MEDICAL GROUP PRACTICE

A study of group practice, begun by Dr. G. Halsey Hunt and Dr. Marcus Goldstein in 1946, has been reported in two articles in *THE JOURNAL* and in a more recent communication on the growth of groups published elsewhere.¹

The purpose of the study is thus stated:

An estimation of the stability of this form of medical practice (group practice) therefore should be of specific interest. The present report attempts such an estimation based on longevity and growth in staff members of a fairly large proportion of existing groups.

The sample from which Dr. Goldstein's information was derived was 98 medical groups in existence during 1947. The field work was conducted by members of the United States Public Health Service on routine duty who visited certain selected groups along their route of travel. These 98 groups include more than one fourth of the 368 groups listed by Hunt in the 1946 survey.²

These 98 existing groups are examined with respect to the relationships between size and age of groups, size of community in which the groups are located, increase in the size of the groups from the date of inception, and physician "turnover." The data reaffirm previous results.³ The largest number of groups are found in communities of less than 10,000; the groups in the larger population centers tend to have more members. Dr. Goldstein finds that the mean age of 98 existing groups is 19.9 years; most of them retain the majority of their original members and 82 per cent

of these groups have increased in size since their beginning.

By "stability" the survey apparently attempts to measure the success and popularity among physicians of group organization as a method of practicing medicine. If several organizations of a certain type for practicing medicine (groups) have been in existence for some time and have lost few members for causes other than death, the investigator assumes that the stability of this type of organization has been demonstrated. This study cannot, however, be considered a definitive study of the mortality or stability of groups but must rather be considered as merely a study of surviving groups in 1947. Examination of the successes supplies no information on the failures and thus on the stability of group practice as a whole. Knowing only the numbers who survived through a given span of years, an actuary cannot establish a mortality table; he must know also the original number alive at the beginning of the period. Only the strong survive in nature, and this is probably true also for group practice.

At the beginning of his article Dr. Goldstein notes that an examination of disbanded groups would be necessary for a complete discussion of the growth of medical groups. His conclusion limits the evidence of stability to "many instances."

This study contributes to our knowledge of medical groups, but should be read in its true setting as an interesting, retrospective study of existing groups. The paper also throws some light on medical vacancies among groups that should be of interest to physicians beginning practice. Some 42 of the examined groups are planning to increase their staffs; otolaryngologic specialists are in most demand and general practitioners the least.

STREPTOMYCIN

In 1944, Herrell reported that "a rather striking suppressive effect on the course of tuberculosis of guinea pigs was obtained" by treating the animals with streptomycin at varying intervals. As nearly as arbitrary numerals could express it, the tuberculosis index of infection controls was 81.9 as compared with 2.8 for the treated.¹ At the time streptomycin was said to have a suppressive effect on human tuberculosis infection in guinea pigs in addition to being well tolerated by the animals. However, not all early students were so enthusiastic.² In the fall of 1946 and after it had been demonstrated that streptomycin had definite therapeutic potentialities in the treatment of clinical tuberculosis, large quantities of streptomycin became available for clinical tests. Such tests were urgent because of the numerous reports of cures and for the purpose

2. Corper, H. J., and Cohn, M. L.: The Tubercle Bacillus and Fundamental Chemotherapeutic and Antibiotic Action, Yale J. Biol. & Med. 19:1-22, 1946.

of determining (1) the types of pulmonary tuberculosis most likely to benefit from the use of streptomycin; (2) the most satisfactory methods and frequency of treatment; (3) the optimum daily dosage; (4) the optimum duration of treatment; (5) the most timely integration of streptomycin with other therapeutic procedures; (6) the significance of less sensitive strains to the drug; (7) the significance of serious toxic manifestations, and (8) relapse of the disease.

Results in summary form³ are now available on 332 patients with pulmonary tuberculosis treated with streptomycin. The degree of therapeutic efficiency of streptomycin is definitely related to the character of the pulmonary disease, with improvement greater in predominantly acute disease than in predominantly chronic disease. As the progression of chronic tuberculosis is fundamentally related to the occurrence of acute episodes, the great potentialities of the strategic use of short courses of streptomycin to combat such episodes should be stressed. Larger doses of streptomycin appeared to be favored over smaller daily doses, but this advantage was often minimized or nullified by severe toxic manifestations incident to larger dosage. Hope is placed in the future use of dihydrostreptomycin to solve this. However, many of the questions poised in 1946 are still unanswered. The "drug fastness" is unquestionably a significant factor in limiting the effectiveness of the antibiotic streptomycin. The phenomenon appears to be common to both streptomycin and dihydrostreptomycin.⁴ Significantly, the failure to close cavities and suppress sputum in a larger percentage of patients and the relapse of the disease with increasing frequency after time has elapsed suggest the limitations of this antibacterial therapy for this characteristically chronic disease. The absolute necessity of using more definitive treatment, notably collapse therapy, to obtain more lasting results is emphasized also.

Even after such enormous amounts of clinical data have been accumulated many of the questions regarding the exact mechanism of action of streptomycin in vitro and in vivo remains a mystery. Although it now appears that streptomycin and allied antibiotics are beneficial agents in pulmonary tuberculosis in only definitely defined conditions and periods of infection, and then only within the limitations of "drug fastness," a wholehearted and serious effort should be made to determine the mechanism of action of streptomycin in tuberculosis. In this way and this way only will its inadequacies be overcome and a better understanding of tuberculosis itself ensue. Review of the history of chemotherapy in tuberculosis is disheartening. Tuberculosis is still a disease of major significance, and sanatoriums are still necessary.

TONSILLECTOMY DURING EPIDEMIC POLIOMYELITIS

THE JOURNAL,¹ March 21, 1942, warned that poliomyelitis, particularly the bulbar form, greatly increased in children after tonsillectomy or adenoidectomy in epidemic areas. Reports of Stillerman, Fischer, Maxwell, Marks, Top, Aycock and Sabin were cited. Since that time avoidance of such operations during epidemics has been almost universally adopted. Recently, otolaryngologists seem inclined to the belief that a causal relationship does not exist between the two and that bulbar poliomyelitis following tonsillectomy is probably purely coincidental. Cunning,² as a result of a survey conducted at the request of the American Laryngological, Rhinological and Otological Society, based on questionnaire survey data covering 1947, felt that the operation should not be indefinitely postponed simply because summer months are the months that poliomyelitis is prevalent. Cunning's report and other factual material relating to this question were recently reviewed by Faber.³ Data on 4,331 cases of poliomyelitis occurring in twenty-five states during 1947 which had been reported by Cunning were reexamined. Incidence of the bulbar type of poliomyelitis was noted to be 25 per cent in the group who had been subjected to tonsillectomy within two months of onset. Incidence of the bulbar type in the entire group was 11.7 per cent. Corresponding figures for 1946 showed an incidence of 29 per cent bulbar type of poliomyelitis among the post-tonsillectomy cases as compared with 15.4 per cent of the bulbar type in the entire group. Thus the incidence of cases of bulbar type was more than twice as great in patients who had been subjected to tonsillectomy as in those who had not been. A previous statistical study by Anderson⁴ of poliomyelitis in Utah in 1943 showed incidence of cases of bulbar type in the general child population to be 25 per 100,000 as compared with 404 per 100,000 in children who had recently had tonsillectomies. Faber concluded that proofs previously offered for a causal relationship between incidence of poliomyelitis and tonsillectomy during epidemic times were still valid and that evidence for this had not been refuted by the Cunning survey.

The weight of past and recent evidence favors the existence of such a relationship. As tonsillectomy is an elective operation which rarely requires immediate surgical attention, the preventive attitude of delay is justified. Until conclusive evidence is presented that such procedures do not increase incidence of poliomyelitis the inadvisability of operation during periods of epidemic poliomyelitis should be emphasized.

Current Comment

MULTIPLE SCLEROSIS SURVEY

The National Multiple Sclerosis Society announces a statistical research on the prevalence and geographic, climatologic and racial characteristics of multiple sclerosis. Dr. Leonard Kurland, epidemiologic statistician of the United States Public Health Service, is directing the survey in the field. Already New Orleans has been surveyed, and surveys are in process in San Francisco and in Denver. The society anticipates that the complete survey will require about a year for completion. Announcements are being made from radio stations concerning the survey with the hope that known cases will be reported to the National Multiple Sclerosis Society, 270 Park Avenue, New York City, giving the name of the patient. This plan has been endorsed by several official agencies.

REGISTRATION UNDER THE HARRISON NARCOTIC ACT

Physicians who are registered under the Harrison Narcotic Act or under the Marihuana Tax Act must effect registration on or before July 1 to avoid a penalty. Each year, despite the annual warnings in *THE JOURNAL*, this requirement is overlooked by some physicians and unpleasant consequences follow. Failure to register adds a penalty of 25 per cent to the tax payable and in addition subjects the physician to the possibility of a fine not exceeding \$2,000 or imprisonment for not exceeding five years, or both. As an act of grace the Commissioner of Internal Revenue has in past years given some tardy registrants the choice between paying sums by way of compromise, a procedure authorized by law, or accepting criminal prosecution. If this procedure does not produce the required promptness in reregistration, the commissioner will have no other alternative than to institute criminal prosecution.

THE RUTGERS INSTITUTE OF MICROBIOLOGY

Dr. Robert C. Clothier, president of Rutgers University, has announced that the University will establish an Institute of Microbiology costing approximately \$1,000,000. Dr. Selman A. Waksman will be its first director. Funds for a \$1,000,000 building to house the institute and a grant of \$250,000 toward its operating expenses will come from royalties on the streptomycin patent. Operating income will be provided in part by the royalties, with University funds and grants from private sources making up the remainder. Dr. Waksman, an alumnus of Rutgers and a member of its staff for more than twenty-five years, assigned his patent to the Rutgers Research and Endowment Foundation with the understanding that any net profits would be used to further research, particularly in microbiology. The new institute will not only give Dr. Waksman and his associates greatly increased facilities for expanding research in microbiology but will make possible an increased program of graduate teaching to insure a supply of young men and women trained to

carry on this work. Establishment of the new Institute of Microbiology as a major branch of the state university will, according to Dr. Clothier, permit a full scale exploration of the potentialities of micro-organisms as instruments for human betterment. Equally important with the fundamental and applied research will be instruction at the graduate level so that greater numbers of future scientists can benefit from the learning and experience of Dr. Waksman. Dr. Waksman's decision to place the proceeds from the royalties accruing from his discoveries into further scientific research is another measure of the stature of this outstanding scientist. Streptomycin, the antibiotic drug which provided the long-sought treatment for many forms of tuberculosis, influenza meningitis, cholera, plague, stubborn urinary and blood infections, certain intestinal infections and undulant fever, was patented by Dr. Waksman in 1945. This and eight other Waksman patents have been assigned to the Research and Endowment Foundation. "Evidence is accumulating," states Dr. Waksman, "that we have but scratched the surface of the potentialities of microbiology, not only in medicine, but in agriculture, industry and all other fields of human endeavor."

AMPHETAMINE INTOXICATION

Popular attention has again been directed by radio commentators and others to the fact that benzedrine® has been used by prisoners as a means of stimulation. Since benzedrine®, or amphetamine, is the chief ingredient of inhaling devices widely used in the United States, access to the product is not difficult. Actually a Congressman has prepared a bill suggesting that amphetamine be placed on the narcotic list, although the drug is not in any sense a narcotic, nor is there any evidence that it is addictive. The persons who use amphetamine are apparently those who try all sorts of drugs as stimulants of sensation, including alcohol, marihuana and bromides as well as the usual narcotic preparations. The prisoners who use amphetamine usually open the inhaler and remove the filler. When the filler is soaked in alcohol or water, the drug passes into solution, and if the entire contents of an inhaler are taken at one time, definite stimulation results. Recently evidence became available that women were smuggling the drug into certain prisons. The effects of the stimulation are manifest in irritability; prisoners start fights and even riots, and may resort to sexual attacks. Some newspapers have referred to the use of the product by the "teen agers," who in some instances have dropped the fillers into carbonated or alcoholic drinks with the hope that the stimulus resulting will enable them to perform more efficiently in the more excitable forms of dancing—such as "jitter-bug," "cut a rug" and what not! Indeed among the "teen agers" this form of stimulation is now known as a "bene jag." The lives of those responsible for the control of the drugs seem to be a continuous succession of attempts to meet new problems resulting from the unwarranted use of drugs for purposes unrelated to medicine.

ORGANIZATION SECTION

Official Notes

ESTABLISH NATIONAL COMMISSION ON CHRONIC ILLNESS

A National Commission on Chronic Illness was formally launched May 20 at a luncheon meeting in Chicago, at which time Mr. Leonard W. Mayo, Cleveland, vice president of Western Reserve University, was installed as chairman of the commission. The speaker at the luncheon was Dr. Leonard A. Scheele, Surgeon General of the U. S. Public Health Service, whose subject was "The Turning Point in Our Care of the Chronically Ill."

The commission is an outgrowth of the Joint Committee on Chronic Disease, set up in 1946 through the cooperative efforts of the American Hospital Association, the American Medical Association, the American Public Welfare Association and the American Public Health Association. In May 1948 the National Health Assembly, held in Washington, D. C., recommended that the Joint Committee on Chronic Disease be expanded to a national commission, with increased membership, backing and responsibilities. The joint committee constituted itself a National Interim Commission on Chronic Illness, under the chairmanship of Dr. James R. Miller of Hartford, Conn., who, as a representative of the American Medical Association, was one of the original members of the Joint Committee on Chronic Disease.

Office space for the commission is being provided by the American Medical Association, which, with other voluntary health and medical organizations, is supporting the commission's work by a financial contribution. The members of the interim commission representing the four national professional organizations remain as members of the permanent body. They are, in addition to Dr. Miller, who becomes vice chairman of the permanent commission: J. Douglas Colman and Dr. Albert A. Snoke, representing the American Hospital Association; Dr. Thomas A. McGoldrick, representing the American Medical Association; Drs. Dean W. Roberts and Edward S. Rogers, representing the American Public Health Association, and Dr. Ellen C. Potter and Judge Thomas S. Waxter, representing the American Public Welfare Association.

The Commission will have thirty members, all of whom will serve without remuneration. They include prominent citizens from all parts of the country, representing the broad fields of industry, medicine, education, labor, farming, religion, public health and hospital administration, as well as the general public. Among them are: S. Bruce Black, president of the Liberty Mutual Insurance Company, Boston; Miss Sarah Blanding, president of Vassar College; Joseph W. Fichter, Master of the Ohio State Grange; Walter Reuther, president of the United Auto Workers, C. I. O.; Dr. Thomas Parran, dean of the Graduate School of Public Health, University of Pittsburgh; Dr. Ward Darley, dean of the School of Medicine, University of Colorado; Karl P. Meister, Executive Secretary, Board of Hospitals and Homes of the Methodist Church, and Mrs. Joseph T. Ryerson of Chicago.

The commission will have expert counsel and guidance from a group of thirty-two technical advisors, selected on the basis of their accomplishments in the five fields which will be most pertinent to the commission's work: clinical problems (including prevention and research); institutional care (including hospitals and nursing homes); noninstitutional care; rehabilitation and convalescence, and community problems. The technical advisors held all day meetings to draw up a program of objectives for the new commission. Chairmen for these group meetings were Dr. Ernst Boas, New York; Dr. Jack Masur, National Institutes of Health, Bethesda, Md.; Dr. Martin Cherkasky, New York; Dr. Howard Rusk, New York, and Dr. Lester Breslow, chief of the Chronic Disease Division, California State Department of Health.

SEVEN STATES NOW

Three more states have recently joined the parade of state legislatures which have petitioned the United States Congress not to pass legislation providing for compulsory health insurance. This makes a total of seven states to date expressing objection from one or both houses to the federalization of medicine. The latest state legislatures to act are Michigan, Florida and Maryland. The Delaware legislature passed such legislation, but it was vetoed by the Governor.

Washington Letter

(From Our Regular Correspondent)

May 30, 1949.

Compulsory Insurance Chief Issue as Hearings Open

Some of the nation's leading opponents and defenders of national compulsory health insurance testified before Senate and House committees during the first week of hearings on the Taft, Hill and Thomas-Murray-Dingell bills. The House hearings have been recessed until June 7, but those under way in the Senate are being continued until the week of June 13, when there will be a one week hiatus.

Senate committee witnesses in the first week, beginning May 23, included J. Donald Kingsley, Assistant Federal Security Administrator; Senators Taft and Hill; Dr. Louis H. Bauer, for the American Medical Association; Dr. Lowell S. Goin, California Physicians' Service; Dr. Carl O. Flagstad, American Dental Association, and Seymour E. Harris, Americans for Democratic Action.

Among those who appeared before the House committee, whose hearings opened on May 20, were Dr. R. L. Sensenich, American Medical Association; Dr. Channing Frothingham and Albert D. Lasker, Committee for the Nation's Health; Dr. Flagstad and Mr. Kingsley.

Public attendance was large at both hearings. Senator James E. Murray (Democrat, Montana) and Representative J. Percy Priest (Democrat, Tennessee) presided over the respective sessions.

Dr. Bauer described the Thomas-Murray-Dingell plan (S. 1679) as "an extreme example of compulsory paternalism, wrong in principle, impossible of practical operation and contrary to our established ways and habits of life and political principles." With reference to the supply of physicians, he observed that medical education does not present an acute problem and it can take care of the needs without government intervention.

Dr. Sensenich, whose direct statement was substantially the same as that presented on the other side of the Capitol by Dr. Bauer, underwent intensive questioning by members of the Priest committee, particularly Representatives Sadowski (Democrat, Michigan), O'Hara (Republican, Minnesota), Biemiller (Democrat, Wisconsin) and Wilson (Democrat, Oklahoma). In the course of interrogation, Dr. Sensenich brought out the following points: Adoption of the American Medical Association policy on government aid to medical schools is in abeyance pending outcome of current investigations on the subject; passage of the National Science Foundation bill is favored by the American Medical Association; insinuations that the American Medical Association is attempting to hold down the number of medical students in this country are without foundation in fact.

Dr. Goin, in his testimony, struck back at accusations made against the American Medical Association's educational campaign, especially by Representative Dingell (Democrat, Michigan) in the statement which he read to the Priest committee on the opening day (May 20) of the hearing.

"The American Medical Association—openly, frankly and honestly—is engaged in a National Education Campaign to give

the people the facts about compulsory health insurance and the facts about voluntary health insurance," he said. "We frankly oppose the first and we enthusiastically favor the second. We hope and believe that the American people, given the facts, will agree with us."

If this campaign, he added, is lobbying, then "it is lobbying in the finest American tradition and every doctor is proud of his part in the program."

Testimony in support of compulsory health insurance legislation was offered by Dr. Frothingham, Mr. Lasker, Mr. Kingsley and Professor Harris, who is professor of economics at Harvard.

Support of the various national health bills they are co-sponsoring was presented to the Murray committee by Senators Taft (S. 1581), Hill (S. 1456) and Thomas (S. 1679). "There is no question that S. 1679 would lead to nationalization and socialization of medicine," Senator Taft stated under a brisk interrogation by Senator Humphrey, a co-sponsor of that measure.

Antibiotic Certification Bill Advances

The House on May 16 passed H. R. 3151, which would add aureomycin, bacitracin and chloramphenicol to the list of drugs which must undergo federal inspection before distribution. On the same day, a companion bill (S. 1867) was introduced in the Senate to expedite consideration in that branch of Congress of the proposed amendment to the Federal Food, Drug and Cosmetic Act of June 25, 1938. Under present law, samples from every batch of insulin, streptomycin and penicillin manufactured for sale must be tested in Washington laboratories of the Food and Drug Administration prior to release in trade channels. The new legislation, if enacted and approved by the President, will make aureomycin, bacitracin and chloramphenicol (chloromycetin®) subject to the same controls.

Health Assembly Report Due In July

July 13 is the tentative publication date for "America's Health: A Report to the Nation," the official résumé of the National Health Assembly held in Washington in May 1948. The volume, containing some 400 pages, will carry findings and recommendations of each of the fourteen professional sections into which the assembly was divided. In addition, there will be a chapter on international cooperation for protection and promotion of public health. The book is being published by Harper's, and its price is expected to be \$4.50. Special discounts will be granted on quantity orders, as well as orders by accredited delegates to the Assembly.

Bureaucracy "Out of Control," Says Sen. Byrd

"It appears that the bureaucracy is out of control with respect to personnel and drastic action is necessary," Senator Harry F. Byrd (Democrat, Virginia) warned on May 19. The senior senator from Virginia, one of the foremost Democratic opponents of compulsory health insurance, asserted that the federal payroll has increased by 146,541 employees since January 1948.

Coming Medical Meetings

American Medical Association, Atlantic City, June 6-10. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

American Association of Railway Surgeons, Chicago, Drake Hotel, June 30-July 2. Dr. Chester C. Guy, 5800 Stony Island Ave., Chicago 37, Secretary.

American Neurological Association, Atlantic City, Chalfonte-Haddon Hall, June 13-15. Dr. H. Houston Merritt, 710 W. 168th St., New York 32, Secretary.

Idaho State Medical Association, Sun Valley, June 20-23. Dr. Alfred M. Popma, 220 N. First St., Boise, Secretary.

Maine Medical Association, Poland Spring, Poland Spring House, June 19-21. Dr. Frederick R. Carter, 142 High St., Portland 3, Secretary.

New Hampshire Medical Society, Newcastle, Hotel Wentworth, June 14-15. Dr. Carleton R. Metcalf, 5 S. State St., Concord, Secretary.

Society for Investigative Dermatology, Atlantic City, Ritz Carlton Hotel, June 11-12. Dr. S. William Becker, 55 E. Washington St., Chicago 2, Secretary.

Society of Biological Psychiatry, Atlantic City, Chalfonte-Haddon Hall, June 12. Dr. George N. Thompson, 1136 W. Sixth St., Los Angeles, Secretary.

Medical Legislation

STATE LEGISLATION

Alabama

Bills Introduced.—H. 46 proposes an appropriation of \$3,000,000 annually to a hospital and planning construction fund. H. 124 proposes the creation of a state medical education board to provide loans and scholarships for students desiring to study medicine. H. 131 proposes to provide for twenty-five scholarships for the study of medicine at the University of Alabama Medical College, the persons selected to be chosen by the State Board of Health in consultation with the Dean of the University of Alabama Medical College. Recipients accepting a scholarship must agree to practice medicine for five years after the completion of medical training in an area of the state designated by the State Board of Health or else repay the amount of the scholarship immediately. H. 178 and S. 187 propose the creation of a scholarship program for advanced study in nursing to be administered by the state board of nurses' examiners and registration. S. 160 proposes to authorize the state board of health to provide an annual program throughout the state for the early diagnosis of cancer. Persons would be urged to report voluntarily to a duly licensed physician of their choice for an official examination, and anyone unable to pay the cost of such examination could register with the county health officer and arrange for a free examination. S. 198 proposes to provide for the examination of all children having congenital or acquired malformations. The county health officer would urge the parents of such children to arrange for an examination by a practicing pediatrician, orthopedist or physician of the parent's choice. If the parents are not able to pay for such examination the county health officer would make the examination or arrange to have it made at a "Well-Baby Clinic" or some other qualified clinic.

California

Bill Introduced.—S. 961 proposes the enactment of regulations for the licensing of analytical toxicologists and defines analytical toxicology as the analysis of any substance for the detection of poison.

Connecticut

Bill Introduced.—S. 1046 proposes to eliminate from the exemption section of the medical practice act persons practicing massage or Swedish movement.

Florida

Bills Introduced.—H. 189 proposes to bind the state by a regional compact looking toward the establishment and maintenance of jointly owned and operated regional educational institutions in the Southern states in the professional, technologic, scientific, literary and other fields so as to provide greater educational advantages and facilities for the citizens of the several states who reside within such regions. One of the institutions to be operated by this regional group would be the Meharry Medical College of Nashville, Tenn. H. 763 proposes the establishment of a medical school and college in Imperial Polk County, Fla. H. 775 proposes to authorize the state board of health to conduct research relating to the causes, prevalence and prevention of diabetes, to distribute information obtained therefrom for education of the public and to purchase at the lowest and best bid from a reliable manufacturer insulin of high quality for distribution for the treatment of indigent persons suffering from diabetes. H. 1087 proposes that no person, partnership, association or corporation shall establish, conduct or maintain a chiropractic hospital, sanatorium or related institution in the state without first obtaining a license from the State Chiropractic Board of Examiners. S. 550 proposes that the tuberculosis board shall provide adequate facilities for the compulsory isolation and treatment of persons found to be suffering from tuberculosis. S. 837, to amend the law relating to dead bodies, proposes that whoever buys, sells or has in his possession for the purpose of buying or selling or trafficking in the dead body of any human being shall be punished by imprisonment; provided, however, that nothing would prohibit the obtaining, dissecting, using and disposing of dead bodies for the purpose of teaching or other appropriate university research by any medical school, dental school, school of nursing or other university research or teaching unit which is a part of a regularly established or chartered institution of higher learning under the laws of the state of Florida.

Illinois

Bill Introduced.—H. 937 proposes regulations for the organization of health services plan corporations to furnish voluntary health services. A voluntary health services plan is defined as a plan or system under which medical, hospital, dental, nursing and related health services may be rendered to a subscriber or beneficiary at the expense of a health services plan corporation.

Oklahoma

Bill Introduced.—S. 301 proposes to authorize the state department of public health to create and maintain a cancer control division to promote a program for the prevention of cancer.

Texas

Bill Introduced.—H. 915 proposes to amend the 1949 basic science law by exempting therefrom graduates of schools of the healing arts who have been enrolled in their respective schools for at least one year prior to the time this act became law and who have attended the schools under the G. I. Bill of Rights and were bona fide residents of the state at the time they entered the military service, provided that this section shall not apply to any person who entered the military service after Jan. 1, 1946.

GOVERNMENT SERVICES

SECRETARY OF DEFENSE

UNIFICATION OF MEDICINE IN THE ARMED SERVICES

Acting to unify administration and operation of the medical services of the armed forces, Secretary of Defense Louis Johnson has established a medical services division within the Office of the Secretary of Defense.

The Secretary's directive provides for the appointment of a director of medical services for the National Military Establishment. He will have responsibility and authority to establish and control general policies, standards and programs for the medical services of the three military departments and related National Military Establishment agencies. In addition, Secretary Johnson set up an autonomous medical department for the Air Force, which heretofore has been served by personnel from the Army Medical Department. The new Air Force Medical Department will be headed by Major General Malcolm C. Grow, the Air Surgeon, who will retain that title.

The three military medical departments will retain their entity under Secretary Johnson's directive, but will operate under supervision by the National Military Establishment Medical Services Division similar to the strategic direction which the Joint Chiefs of Staff give to the unified commanders of the military departments.

The Director of Medical Services may be a civilian or an officer of one of the armed services. He will be appointed by the Secretary of Defense. His duties are defined as: (1) establishment and control of general policies, standards and programs for the medical services of the three military departments and appropriate agencies of the National Military Establishment; (2) to exercise general direction, authority and control over administration and utilization of personnel and facilities of the medical services of such departments and agencies through the heads thereof, and (3) such other duties with respect to the medical services of the National Military Establishment as the Secretary of Defense may direct.

In creating the National Military Establishment Medical Services Division and providing for an autonomous Air Force

Medical Department, Secretary Johnson acted on the advice and recommendation of his Medical Advisory Committee, to which a recommendation of the Joint Chiefs of Staff that studies be made of measures intended to produce a unified National Military Establishment Medical Service was submitted. Charles Proctor Cooper, president of the Board of Trustees of Presbyterian Hospital in New York, is chairman of this committee, which is composed of eleven civilian physicians and dentists, the Surgeons General of the Army and Navy and the Air Surgeon.

With the establishment of the Air Force Medical Department, Secretary Johnson authorized the transfer to it for temporary duty of 100 Army and 100 Navy medical officers to help meet the shortage of medical personnel in the Air Force.

General hospitals serving Army and Air Force personnel will continue to be operated by the Army. Secretary Johnson also directed that general hospital training facilities of the Army and Navy be made available to the Air Force Medical Service on an equitable basis.

FIRST MEDICAL VOLUNTEERS CONGRATULATED

Secretary of Defense Louis Johnson on May 13 congratulated the first two young professional men who responded to the appeal for volunteers to overcome the shortage of physicians in the armed forces.

They are: First Lieut. James L. Patterson Jr., of Duncan, Okla., the first physician to volunteer for the Army, and Lieut. (jg) Milton M. Lownes Jr., of Philadelphia, the first physician to volunteer for the Navy.

The ceremony was held in the office of the Secretary of Defense in the Pentagon. The two young volunteers were introduced to Secretary Johnson by the heads of their respective medical departments, Major General Raymond W. Bliss, Surgeon General of the Army, and Rear Admiral Clifford A. Swanson, Surgeon General of the Navy.

ARMY

NATIONAL GUARD OFFERS COMMISSIONS TO MEDICAL GRADUATES

The 1949 medical school graduates who are not enrolled in R.O.T.C. medical units are being invited to accept commissions in the National Guard, Major General Kenneth F. Cramer, Chief, National Guard Bureau, announces.

Persons graduating from accredited medical schools this summer and beginning to serve their internships may be commissioned immediately as first lieutenants in the National Guard without previous military service.

"Under this program, young doctors and dentists are afforded an opportunity to identify themselves with National Guard outfits in more than 2,000 cities and towns throughout the forty-eight states, the District of Columbia, Hawaii and Puerto Rico," General Cramer stated.

Those who served in a commissioned capacity during World War II may receive commissions one grade higher than normally called for by the unit vacancy to which they would be assigned, provided they served in the higher grade during the war.

Doctors are particularly needed in time for service with the National Guard during the coming summer field training—most extensive in Guard history, with some 5,000 federally recognized Army and Air units participating.

R. O. T. C. SUMMER TRAINING

Medical students from professional institutions with one year or more of active military duty will participate in the summer training camp program at one of eight Army general hospitals instead of the previously planned training at the Medical Field Service School, Fort Sam Houston, Texas. This change is designed to place primary emphasis on military medicine, omitting a number of subjects of a purely military nature.

These revisions do not affect other medical R. O. T. C. students who are nonveterans. The nonveteran group will take part in the summer training program conducted at Fort Sam Houston.

Attendance at the general hospital camps is limited to students who have completed the sophomore year of their respective professional field in college. A qualified veteran, slated for Army general hospital training, may attend the field school at Fort Sam Houston if he so desires.

The period of the summer training program is June 13-September 9. This period is divided into two separate camps. The first will open June 13 and the second July 31; each lasting six weeks. The only exception to this Department of the Army ruling is for the first camp conducted at Letterman

General Hospital, San Francisco. There training will be given to medical students only, beginning May 31 and ending July 9.

During the summer at the Army general hospitals, these students will receive a minimum of orientation concerning military matters and, for the most part, will spend their time in the wards. They will attend as many of the regular formal teaching exercises as can be integrated into their program. Residents, interns and the attending staff assigned to the general hospital will furnish the bulk of the teaching. With few exceptions, the Army hospitals in which R. O. T. C. students will train are at present participating in medical training programs in nearby civilian institutions.

The eight Army general hospitals to be utilized this summer are as follows: Walter Reed, Washington, D. C.; Oliver, Augusta, Ga.; Percy Jones, Battle Creek, Mich.; Brooke, Fort Sam Houston; Fitzsimmons, Denver; Letterman, San Francisco; Madigan, Tacoma, Wash., and Valley Forge, Phoenixville, Pa.

ADVANCED TRAINING IN CIVILIAN INSTITUTIONS

The following Army Medical Department officers have been selected for advanced training in civilian institutions:

Joseph A. Connor Jr., Major	George Washington University School of Medicine, Wash- ington, D. C.	Internal medicine
Thomas P. Jernigan III, Capt.	Baltimore City Hospitals	Medicine
Marvin D. Blackburn Jr., Capt.	St. Paul's Hospitals, Dallas 4, Texas	Pathology
John B. Sheffer, First Lieut.	Buffalo General Hospital	Pathology
John J. Carter, First Lieut.	University Hospital, Little Rock, Ark.	Obstetrics and gynecology
William P. Barron, First Lieut.	University Hospital, Little Rock, Ark.	Pediatrics
William W. Tucker, First Lieut.	Franklin Hospital, San Fran- cisco	Medicine
Richard B. Johnson, First Lieut.	Indianapolis General Hospital	Intern training
Francis P. Martin, First Lieut.	Kings County Hospital, Brooklyn	Intern training

NAVY

NAVY LOANS 100 MEDICAL OFFICERS TO THE AIR FORCE

The Secretary of Defense on May 13, 1949, directed that thirty-five Naval medical officers be assigned temporarily to the U. S. Air Force for duty; sixty-five additional Navy medical officers are to report at a later date to be set by the Director of Medical Services of the National Military Establishment. The services of these doctors are urgently required by the Air Force until such time as doctors are procured to staff its own medical department.

This directive should not be construed as an indication that the Navy Medical Department is in excess, or has obtained its quota, of medical officers as the result of the current procurement program for doctors.

Regular and reserve medical officers now on active duty, and inactive reserve medical officers may volunteer for assignment to the Air Force. Those who request overseas duty will be permitted to take their families to the overseas Air Force facilities. These doctors will not be commissioned in the Air Force but will serve as Naval medical officers and wear the Navy uniform while so serving.

It is contemplated that, if those who volunteer have not already qualified as flight surgeons or aviation medical examiners, they will be ordered to Randolph Field, Texas, for a four week course of instruction in the technic of aviation examination and then assigned to Air Force facilities within the continental United States for duty, provided they have not previously indicated a preference for overseas duty. The maximum tour of duty with the Air Force has been set at two years.

Regular and active officers should submit applications to the Bureau of Naval Personnel via the Bureau of Medicine and Surgery. Inactive reserve officers should submit applications to the commandant of their local Naval District. Applications should be submitted prior to June 15, 1949.

REAR ADMIRAL ADAMS RETIRES

Rear Admiral John C. Adams, M.C., a pioneer naval flight surgeon, was transferred to the retired list on April 1 after more than thirty years of naval service. For outstanding services as flight surgeon in charge of the Division of Aviation Medicine, Bureau of Medicine and Surgery, during World War II, he was awarded the Legion of Merit. He received the John Jeffries Award from the Institute of Aeronautical Sciences for contributions to aviation in medical research for 1945.

NEW REGULAR OFFICERS

The following reserve medical officers have been appointed to the Medical Corps of the Regular Navy: Comdr. William S. Lawler, Lowell, Mass.; Comdr. Hermann J. Lukeman, New York, and Lieut. (jg) Victor G. Benson, Soldier's Grove, Wis.

FIRST ACTIVE DUTY AT NAVAL FACILITIES

The following lieutenants (jg) of the Medical Reserve Corps have been nominated for their first active duty at the Naval medical facilities indicated:

Name	Residence	Naval Facility
Adams, Barnette E. J., Jr.	New Orleans	Air Technical Training Center, Memphis, Tenn.
Austin, Robert R.	Dixon, Ill.	Naval Hospital, San Diego, Calif.
Kutschbach, Melvin A.	Houston, Texas	Naval Hospital, Corpus Christi, Texas
Settimi, Albino L.	Whittier, Calif	Naval Hospital, Corona, Calif.
Shershin, Peter H.	Clifton, N. J.	Naval Training Station, Newport, R. I.
Van Dwyne, Charles M.	Pontiac, Ill.	Naval Dispensary, San Francisco

APPOINTMENT FOR POSTGRADUATE INSTRUCTION

The following medical officers have been nominated for postgraduate instruction: Comdr. Robert B. Johnson, York, Neb., to a residency in orthopedic surgery at the Naval Hospital, Oakland, Calif., and Lieut. (jg) Donald W. Grimes, Palmetto, Fla., to a residency in internal medicine at the Naval Hospital, Long Beach, Calif.

PERSONALS

Comdr. Ralph Volk, M.C., U.S.N.R., of Rutland Heights, Mass., has been nominated for recall to active duty and will be assigned to the Naval Hospital, St. Albans, N. Y., on completion of a course in internal medicine at Harvard Medical School, Boston.

Commander Peter G. Kroll of Mt. Carmel, Pa., and Lieutenant Francis H. McCullough Jr. of Jackson Heights, Long Island, N. Y., medical reserve officers, have requested recall to active duty and have been nominated to courses of instruction as residents in thoracic surgery and orthopedic surgery at the Naval Hospital, St. Albans, Long Island, N. Y., and the Naval Hospital, Philadelphia, respectively.

Commanders Chalmers R. Carr and Donald C. MacKinnon and Lieut. Comdr. William Charles Mulry have recently been certified by the American Boards of Surgery, Otolaryngology and Radiology, respectively.

Lieut. John H. Hege of Dover, Pa., and Lieut. (jg) Edward D. Loweccey of Pittsburgh have been nominated for their first active duty in the Regular Navy Medical Corps as residents, respectively, in internal medicine at the Naval Hospital, Bethesda, Md., and in internal medicine at the Naval Hospital in Philadelphia.

Lieut. Charles E. Weber of Rochester, N. Y., and Lieut. (jg) Roger K. Wallace of Ravenna, Neb., have been appointed to the Regular Navy Medical Corps from an active reserve status.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Book Plates of Physicians.—The Huntington Library at San Marino is developing a collection of book plates of physicians. Doctors who have book plates of their own or of others are invited to forward copies to the library to be entered in the collection.

New School of Tropical Medicine.—A School of Tropical and Preventive Medicine is to be developed in Loma Linda, in conjunction with the School of Medicine of the College of Medical Evangelists. Both graduate and undergraduate medical students will be given training in tropical medicine. Special short courses will be conducted for nonmedical missionaries preparatory to their departure for overseas posts. Dr. Harold N. Mozar, assistant professor of internal medicine of the school of medicine, has been named director of the new unit. During World War II Dr. Mozar served in New Guinea and was chief of the Communicable Diseases Section of the 47th General Hospital.

Medical Care Section Established.—A new Section in Medical Care Administration has been established by the School of Public Health at the University of California, Berkeley. This new curriculum complements the school's existing programs in hospital management and public health administration. Qualified graduate students may major in medical and hospital administration courses leading to the M.P.H. degree. Dr. Edward S. Rogers, dean of the school, heads the joint division. Dr. E. Richard Weinerman will be in charge of developing the new medical care curriculum. Drs. Sydney S. Norwick, Berkeley, and Dean A. Clark, New York, are part time visiting lecturers in the new section. A small research staff, headed by Charlotte F. Muller, Ph.D., is now engaged in medical economics field studies. The section will also be a repository of factual data in medical economics, and will serve as a source for consultation in problems of medical care, offering technical aid and other help to interested persons or organizations.

CONNECTICUT

Medical Service Plan.—Connecticut Medical Service enrolled 70,000 members in its first ten weeks of operation, representing 772 industrial and business firms. The plan was first offered to the public on February 14. Physicians participating in the plan numbered 1,272 as of May 15. This represents more than 85 per cent of the 1,479 physicians whose type of practice normally includes services covered by the plan. The number is increasing with the continued arrival of new agreements at the state medical society office. Robert S. Judd, president of the Connecticut Medical Service, has announced that the plan expects to pay surgical and maternity bills in volume from now on. The number of subscribers in the surgical plan now represents about 3½ per cent of Connecticut's population.

DISTRICT OF COLUMBIA

Hachmeister Memorial Lecture.—Hachmeister, Inc., of Pittsburgh, has established the A. C. Hachmeister Memorial Lectureship in the department of pharmacology of Georgetown University School of Medicine in memory of its founder and first president. Dr. C. Heymans, professor of pharmacology at the University of Ghent and Nobel Prize Laureate in medicine, 1938, delivered the first lecture May 4 on "The Role of Pressor and Chemo-Receptors in the Regulation of Respiration."

ILLINOIS

Commission for Handicapped Children.—Dr. Gerald M. Cline of Bloomington has been appointed a member of the Illinois Commission for Handicapped Children succeeding Dr. Bert I. Beverly, deceased. The commission is made up of the respective heads of the State Departments of Public Welfare, Public Health, Public Instruction and Labor, together with nine interested citizens appointed from the state at large by the Governor. The commission functions as a coordinating, fact-finding and stimulating agency charged with developing a more adequate statewide program for physically and mentally handicapped children. Dr. Cline is a native of Illinois, a

veteran of World War I and a graduate of the University of Illinois College of Medicine, Chicago. He has been engaged in the practice of medicine since 1922, specializing in pediatrics and allergy. He is also on the advisory committee to the Division of Services for Crippled Children.

Chicago

Free Roentgen Examinations on Northwest Side.—A communitywide chest roentgenologic survey will be held during July and August on the near Northwest Side, which has one of the highest tuberculosis rates in Chicago. The Tuberculosis Institute and the Municipal Tuberculosis Sanitarium will conduct the survey using their two mobile x-ray units. Beginning July 5 free examinations will be made.

Award Willard Gibbs Medal.—The Chicago section of the American Chemical Society awarded its Willard Gibbs Medal May 20 to Peter J. W. Debye, Ph.D., of Cornell University, New York, in recognition of his work with high polymers, the giant molecules that make up rubber, plastics and proteins. Dr. Debye formerly was director of the Max Planck Institute in Berlin.

Home Care for Cancer Cases.—Michael Reese Hospital, under a grant from the Illinois Division of the American Cancer Society, will supply free home care for indigent cancer patients on an experimental basis. The program supplements one already in operation for heart patients. The service is being expanded to include patients with arthritis, diabetes and neurologic disease. Eight physicians from the hospital staff have been assigned to the four month cancer care program.

Acting Head of Division of Anesthesia.—Dr. Max S. Sadove, assistant professor of anesthesia at the University of Illinois College of Medicine, has been promoted to associate professor and acting head of the division of anesthesia. Dr. Sadove, a graduate of the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, has been on the faculty for the past two years. Following his release from the army medical corps after five years' service, he served a residency in anesthesia at the Veterans Administration Hospital, Hines. He will continue to serve as consultant in anesthesia at Hines and at the City of Chicago Municipal Tuberculosis Sanitarium.

KANSAS

Society News.—The Kansas Psychiatric Society elected the following officers for the year ending April 1950: Dr. Clarence J. Kurth, Wichita, president, and Dr. Frank F. Merker, Topeka, secretary-treasurer.

Community Honors Fifty-Year Practitioner.—A city-wide celebration for Dr. James A. McLaughlin, Wichita, was held by the citizens of Greensburg, where he has spent the greater part of fifty years of practice. An open house and tea were held in the community building, and a dinner for all friends and relatives took place at the Baptist Church.

KENTUCKY

Annual Health Conference.—The first annual conference on health in Kentucky will be held June 23 at Warren Memorial Presbyterian Church, Louisville. The all day session will present a statewide view of health problems including those pertaining especially to tuberculosis, mental illness, rural health, medical care and school health.

Appoint Director of Blood Center.—Dr. Alberta B. W. Baugh, Louisville, has been appointed technical director of the Red Cross Regional Blood Center, which was opened by the Mayor of Louisville May 18. The center will collect and supply blood in an area within a 75 mile radius of Louisville. Dr. Baugh is a graduate of the University of Louisville School of Medicine, 1939.

MAINE

Dr. Ames Resigns Hospital Post.—Dr. Forrest B. Ames, Bangor, president of the Maine Medical Association, resigned April 1 as head of the department of roentgenology at Eastern Maine General Hospital after twenty-six years of service. He is opening a private practice in Bangor.

Anniversary Reunion at Jackson Laboratory.—An open invitation has been issued to attend the Roscoe B. Jackson Laboratory's Twentieth Anniversary Reunion of visiting investigators and summer students at Bar Harbor August 18-21. The reunion will be part of the four-day observances, during which dedication ceremonies for the rebuilt laboratory will take place. Because of the destruction of some of the records during the fire of October 1947, the laboratory does not have a complete list of former associates and students. If any one of these

wishes to attend any part or all of the anniversary reunion, he should get in touch with the laboratory at once as there is still a shortage of housing accommodations in Bar Harbor, and full details will be sent.

MASSACHUSETTS

Dr. Cohn Named University Professor.—Edwin J. Cohn, Ph.D., professor of biological chemistry and chairman of the Division of Medical Sciences, Harvard Medical School, Boston, has been appointed a university professor. He is one of four scholars especially chosen for work on the frontiers of knowledge and will be free of obligation to any individual school or department within the university. He will continue his research in physical biochemistry. Dr. Cohn's appointment follows the retirement of Prof. Roscoe Pound, who was the first scholar to hold a university professorship. Dr. Cohn has served in the department of physical chemistry at the medical school since 1922, and has been professor of biological chemistry and head of the department since 1935. He is a graduate of the University of Chicago, 1917, and a recipient of the John Phillips Memorial Medal of the American College of Physicians, 1946, the Passano Award, 1945, and the Alvarenga Prize of the College of Physicians of Philadelphia, 1942. He serves at present on the Panel on Hematology of the U. S. Public Health Service and on the Committees on Blood and Blood Derivatives of the American Red Cross and the National Research Council. He has been an honorary consultant to the Medical Department of the Navy since 1942.

NEW HAMPSHIRE

State Medical Meeting.—The annual meeting of the New Hampshire Medical Society will be held at the Hotel Wentworth, New Castle, June 14-15 under the presidency of Dr. Clarence E. Dunbar, Manchester. Out of state speakers include:

John R. Paul, New Haven, Conn., Clinical Considerations of Acute Poliomyelitis.

J. William Hinton, New York, Significance of Abdominal Pain.

David S. Grice, Boston, Orthopedic Problems and Their Management in the Newborn.

Wallace E. Herrell, Rochester, Minn., Present Status of Antibiotic Therapy.

Frank H. Lahey, Boston, Surgical Management of Lesions of the Terminal Ileum, Colon and Rectum.

Basil C. MacLean, Rochester, N. Y., The Hoopskirts of Hospital Finance.

On Tuesday morning there will be a symposium on the Economic Phases of Hospital Administration with James M. Langley, Concord, president of the Blue Cross in New Hampshire, as moderator. Round table conferences in seven specialties are scheduled for Wednesday morning. At the annual banquet Tuesday at 7 p. m. Sherman Adams, governor of New Hampshire, and Dr. George F. Lull, Secretary, American Medical Association, Chicago, will be the speakers.

NEW YORK

Research on Hemorrhagic Shock.—A grant of \$29,370 has been made to the University of Buffalo by the Veterans Administration for research on red blood cells in relation to hemorrhagic shock. The one year grant was made through the National Research Council, and is renewable as the project continues. The research will be headed by Dr. John D. Stewart, professor of surgery and chairman of the department of surgery in the medical school. There will be three major investigators: Dr. L. Edgar Hummel, a hematologist; Joseph G. Hoffman, Ph.D., a biophysicist, and Dr. Irving Rudman, Buffalo, a surgical assistant, besides three technicians. The project, known as "Physiological Adjustment to Hemorrhage and the Fate of the Transfused Red Blood Cell," will involve the use of radioisotopes, which will be obtained through the Atomic Energy Commission.

New York City

Dr. Selye to Address Alumni.—New York Medical College, Flower and Fifth Avenue Hospitals Alumni Day will be held June 7. Included in the activities will be the second annual Alumni Lecture by Dr. Hans Selye, professor of experimental medicine and surgery, University of Montreal Faculty of Medicine, at 11 a. m. on "Hypertension as a Disease of Adaptation." The annual banquet will be held at 6:30 in the Grand Ball Room, Ritz-Carlton Hotel.

Report on Examinations for Tuberculosis.—The New York Tuberculosis and Health Association reports that 9,119 chest roentgenograms were taken by the Bronx Tuberculosis and Health Committee last year, and 2,783 families and individuals were aided in their health programs. More than 50,000 persons attended meetings, lectures, motion pictures and exhibits

held under committee auspices. During the year 3,842 parochial school pupils had received audiometer tests, and 54 hearing defects requiring attention had been discovered. Dr. Nathan B. Van Etten was reelected chairman of the committee.

OHIO

Personals.—Dr. Morris Schaeffer, assistant professor of pediatrics at Western Reserve University. School of Medicine, Cleveland, and director of the contagious department of the Cleveland City Hospital, has resigned from these posts, effective June 30, and will leave Cleveland to assume new responsibilities as director of the Virus and Rickettsial Research and Epidemiology Branch of the Communicable Disease Center of the U. S. Public Health Service.—Dr. John A. Toomey has returned from his sabbatical leave in Florida to resume his duties as head of the contagious department.—Dr. Calvin L. Baker, superintendent of Dayton State Hospital, has been appointed commissioner of mental hygiene for Ohio.

Short Courses in Poliomyelitis.—At the department of contagious diseases, City Hospital, Cleveland, Dr. John A. Toomey will direct a series of short training courses in poliomyelitis. The dates of the courses for physicians are July 18-23, August 8-13 and August 29-September 3. The National Foundation for Infantile Paralysis will pay the expenses of the enrollee, providing the chairman of his local chapter approves. Meals may be purchased at the hospital, but each enrollee is responsible for his own hotel reservations. There will also be courses for nurses and physical therapists. For complete programs write to Dr. Toomey, City Hospital, Cleveland.

PENNSYLVANIA

Society News.—The Pennsylvania Academy of Ophthalmology and Otolaryngology at its annual meeting April 22-24 in Harrisburg installed Dr. Daniel S. DeStio, Pittsburgh, president and chose Drs. Jay G. Linn, Pittsburgh, president elect, Benjamin F. Souders, Reading, secretary, and Bruce A. Grove, York, treasurer.

Philadelphia

Ex-Interne-Resident Dinner.—The annual dinner of the Ex-Interne-Resident Association of the Hospital of the University of Pennsylvania will be held at the Hotel Sylvania, Philadelphia, June 10 at 6:30 p. m. Subscription will be \$5. Reservations may be secured from John W. Frost, M.D., Hospital of the University of Pennsylvania.

Temple University News.—Recent staff appointments at Temple University Medical School and Hospital include Drs. George D. Vaughan Jr., Philadelphia, instructor in proctology; George W. Russell, Philadelphia, assistant instructor in psychiatry, and Sydney A. Ellis, Boston, associate professor of pharmacology. Recent gifts totaling \$1,388 have been made to the Psychiatric Department Research Fund, and \$5,100 has been received for research in ophthalmology.

New Course in Anesthesiology.—A comprehensive eight month course in anesthesiology will be offered in the Graduate School of Medicine of the University of Pennsylvania beginning in October. The chairman of the newly created department is Dr. Robert D. Dripps, professor of anesthesiology, Graduate School of Medicine, and director of anesthesiology at the Hospital of the University of Pennsylvania. The program will provide training in basic as well as clinical sciences. The university's announcement said that new approaches in pedagogy will characterize the course. Panel discussions and presentations of clinical cases will supplement formal lectures. This section is to be headed by Drs. Julius H. Comroe Jr., Seymour S. Kety, David L. Drabkin and William E. Ehrlich. In an attempt to assure a broad clinical foundation for the anesthesiologist, it was explained, training in cardiology, neurology and radiology will be provided. Clinical preceptorships will be served in eight to ten Philadelphia hospitals in which there are departments of anesthesia staffed by physicians. The course is not intended to compete with or replace a required and supervised residency in anesthesiology in an accredited hospital. Designed after careful thought and with the advice of the American Board of Anesthesiology, it is offered as a supplement, or precursor, to such resident training.

Pittsburgh

\$300,000 Gift for Medical Library.—The University of Pittsburgh has received a gift of \$300,000 from the Maurice and Laura Falk Foundation to construct a medical library in the proposed new school of medicine. The library will be known as the Maurice and Laura Falk Library, and its initial collection will include more than 50,000 volumes. It is to be located on the first floor of the new school and will be officially the library of the Allegheny County Medical Society.

SOUTH CAROLINA

Personal.—Dr. Harry F. Wilson, Columbia, has been elected director of the Division of Laboratories of the South Carolina State Board of Health. He has been serving as acting director of laboratories since July 1947, as well as director of the Division of Industrial Health.

State Medical Association Meeting.—The annual meeting of the South Carolina Medical Association was held at the Ocean Forest Hotel, Myrtle Beach, May 17-19 under the presidency of Dr. Robert B. Durham, Columbia. Guest speakers included:

Edward B. Sheehan, Boston, Carcinoma of the Endometrium.
Frank P. Coleman, Richmond, Va., Treatment of Fractured Ribs.
H. Hudnall Ware Jr., Richmond, Va., Management of Some Usual Obstetrical Difficulties.

WASHINGTON

Breakfast Study Club in Tacoma.—The Tacoma chapter of the American Academy of General Practice has organized a breakfast study club, which will meet on Friday mornings to consider ways and means of making the family doctor available to all people of Tacoma and to keep him abreast of the latest developments in medical science. All physicians are invited to participate in the discussions.

Allen Lecture.—The second annual Raymond B. Allen Lectureship, honoring the president of the University of Washington, was held May 27. The lectureship consisted of a symposium on The Medical Aspects of Nuclear Energy with the following participants: Dr. Joseph G. Hamilton, associate professor of experimental medicine and radiology, University of California, Berkeley, and Dr. Simeon T. Cantril, associate clinical professor of radiology, University of Washington School of Medicine, director of the Tumor Institute, Swedish Hospital, Seattle. This lectureship is sponsored by the local chapter of the Phi Beta Pi Medical Fraternity.

WEST VIRGINIA

Society News.—Dr. Garnett P. Morison, Charles Town, was elected president of the West Virginia Academy of Ophthalmology and Otolaryngology at the annual spring meeting held at Martinsburg May 13-14. Dr. Melvin W. McGehee of Huntington and Dr. Frederick C. Reel of Charleston were reelected secretary and treasurer, respectively.

Temporary Licensing of Interns and Residents.—At a meeting of the public health council at Charleston May 12 regulations were promulgated for the temporary licensing of interns and residents. The regulations were adopted to provide means to alleviate to some extent the critical doctor shortage in rural areas, especially coal mining communities. Participating interns and residents must be graduates of class A medical schools and must be serving in hospitals fully accredited by the American Medical Association or the American College of Surgeons. Applicants and sponsors will be given letters of authorization by the secretary of the medical licensing board, and legal responsibility will be assumed by the sponsor, who will be required to report to the licensing board and the hospital whether or not the services of the relief physician are satisfactory. The time spent on relief work by a doctor shall not exceed thirty days each twelve months of hospital service, and the sponsor will be required to spend a reasonable length of time with the relief doctor for indoctrination. The participating physician will take care of all regular reports, filing of birth and death certificates and communicable disease reports. The relief doctor's signature will be valid on all state documents, insurance papers and compensation reports during the relief period.

WISCONSIN

Veterans Hospital Clinical Day.—Woods Veterans Hospital will hold a Clinical Day program June 30 at the hospital to which all physicians are invited. Drs. Michael F. Koszalka and Albin J. Krygier will be chairmen of the morning and afternoon sessions respectively.

Personal.—Dr. James C. Sargent, clinical professor of urology at Marquette University, Milwaukee, and a captain in the Naval Medical Corps Reserve, has been appointed a member of the Board of Reserve Consultants to the Surgeon General of the Navy.

Research on Arthritis and Rheumatism.—An intensive study of arthritis and rheumatism will be initiated at the University of Wisconsin following a gift of \$10,300 from the Thomas E. Brittingham Trust Fund. Dr. Daniel M. Angevine and Dr. Charles H. Altshuler of the department of pathology,

who have been conducting histochemical studies of rheumatic disease for two years, will receive \$5,300 to finance their work. Four thousand dollars will be used for electromyographic apparatus for the study of muscular changes in arthritic conditions. Dr. Charles V. Seastone of the department of microbiology will use \$1,000 of the gift to investigate sensitization reactions to streptococci in rheumatic and arthritic states.

ALASKA

Anchorage Medical Society.—This society, which was recently organized through the efforts of Colonel Stanley W. Matthews, M.C., U. S. Army, will hold meetings each month, alternating between Anchorage and the 183rd Army General Hospital. The society is open to all physicians, civilian or military, in good standing who live in the vicinity of Anchorage. Officers elected for the current year are: Colonel Matthews, president; Dr. George G. Davis, Anchorage, vice president; Dr. Milo H. Fritz, Anchorage, secretary, and Major Robert B. Franklin, M.C., U. S. Army, treasurer.

PUERTO RICO

Legislation for School of Tropical Medicine.—The Insular Legislature has approved a bill to authorize the Superior Board of Education of the University of Puerto Rico to establish a school of medicine, giving the board also jurisdiction over the administration of the School of Tropical Medicine, San Juan, now operating under the guidance of Columbia University, New York. The School of Tropical Medicine is now under the direction of a board of trustees, five of whom are members of the Superior Board of Education of the University of Puerto Rico, and two of Columbia University. The director and the members of the faculty of this school serve at the will of the board of trustees of Columbia University. The bill, now pending approval of the governor, will change the administration, giving jurisdiction to the University of Puerto Rico.

GENERAL

Phi Chi Luncheon.—Phi Chi medical fraternity will hold a luncheon June 9 at 12:45 p.m. at the Ambassador Hotel in Atlantic City, N. J. Tickets will be available at the Phi Chi registration desk in the fraternity and alumni registration area at Convention Hall.

Railroad Surgeons Meeting.—The annual meeting of the American Association of Railway Surgeons will be held at the Drake Hotel, Chicago, June 30 to July 2, under the presidency of Dr. Raymond B. Kepner, Chicago. A symposium on Intrathoracic Disorders is scheduled for Thursday afternoon and another on Bone and Joint Lesions for Friday afternoon.

Proctology Meeting.—The newly organized International Academy of Proctology will hold its first meeting at the Marlborough-Blenheim in Atlantic City, N. J., June 10. The scientific program will include motion picture films of rectal surgery. Papers on proctologic subjects will be presented by Drs. Earl J. Halligan, Jersey City, N. J.; Edgar M. Scott, Birmingham, Ala.; Caesar Portes, Chicago, and William Lieberman, Brooklyn.

Pamphlets on Cancer Sites.—The American Cancer Society in cooperation with the National Cancer Institute, Bethesda, Md., has prepared four cancer pamphlets. The sites considered are: (1) the breast, and (2) female generative organs, where nearly 40 per cent of cancers fatal to women start; (3) the digestive organs, which account for nearly 50 per cent of all cancer deaths, and (4) the mouth and respiratory tract, including the lungs and bronchus, where reported cancer mortality in men has increased over 300 per cent in the last fifteen years. The pamphlets can be obtained without charge through most of the local or state offices of the society's sixty-one divisions or the national office at 47 Beaver Street, New York City.

Dr. Burnell Succeeds Dr. Selby at General Motors.—Dr. Max R. Burnell, Flint, Mich., will become medical consultant to General Motors Corporation effective July 1, succeeding Dr. Clarence D. Selby, who is retiring after fourteen years of service. Dr. Burnell, a graduate of the University of Michigan Medical School, Ann Arbor, 1918, has been medical director of the AC Spark Plug Division of General Motors since 1931, when he organized it as one of the first certified industrial medical departments in America. Its modern equipment and advanced technics have long been recognized as outstanding in medical circles throughout the country. For many years Dr. Selby has served as a special lecturer at the School of Public Health of the University of Michigan, where, after his retire-

ment, he will assist in the development of a program in the field of industrial health. Last year Dr. Selby inaugurated a cooperative program between the company and medical schools whereby graduates from these schools are able to take their internship in General Motors plants (THE JOURNAL, March 26, p. 864).

Committee on Habit-Forming Drugs.—The World Health Organization has selected Dr. Nathan B. Eddy as chairman of its Expert Committee on Habit-Forming Drugs. Dr. Eddy has been a leader in investigating the use of narcotics in the control of pain in cancer. In 1939 he shared with Dr. Lyndon F. Small of the National Institutes of Health the first annual award of the American Pharmaceutical Manufacturers Association for discovery of the drug metopon. Among his university appointments is that of research professor in pharmacology at the University of Michigan from 1930 to 1939. Dr. Eddy is also secretary of the Committee on Drug Addiction and Narcotics of the National Research Council.

American Society for the Study of Sterility.—This society will hold its annual conference at the Hotel Strand, Atlantic City, N. J., June 6-7 under the presidency of Dr. Lyman W. Mason, Denver. Those presenting papers by invitation include:

Samuel R. M. Reynolds, Ph.D., Brooklyn, Problems in Uterine Physiology and Their Interpretations.

Samuel R. Meaker, Boston, Ovarian Resection for the Relief of Sterility.

Marvin R. Thompson, Ph.D., New York, Nutritional Requirements in Human Reproduction.

James L. Royals, Pittsburgh; Carlton N. Price, Washington, and Paul Titus, Pittsburgh, Hysterosalpingography—Dangers and Their Prevention.

William H. Perloff, Philadelphia, Extraction of Human Hyaluronidase from Human Testes and Semen.

The speaker at the annual dinner Monday at 7 p. m. will be William W. Greulich, Ph.D., of the National Research Council, whose subject will be "Hiroshima and Nagasaki, 1947 and 1948."

Publication on School Health Policies.—Contributing toward the improvement of health programs for school children, which is one phase of the general theme of the 1949 Child Health Day May 1, more than 105,000 copies of "Suggested School Health Policies"—a charter for school health—have been distributed by the Health Education Council. "Suggested School Health Policies" not only has contributed to building a healthier America for American children, but has also contributed to the rehabilitation of the Japanese school system. American Military Government teams have ordered this 48 page guide for use in developing up-to-date school health policies in Japan. The booklet was prepared by a committee representing fifteen national organizations concerned with health and education. It may be obtained from the Order Department, American Medical Association, 535 N. Dearborn Street, Chicago, Ill. The price of the booklet is 25 cents; single copies are free to persons engaged in health education. The booklet can also be ordered in quantity from Health Education Council, 10 Downing St., New York 14.

National Vitamin Foundation.—Dr. E. Gifford Upjohn, vice president, the Upjohn Company, Kalamazoo, Mich., was elected president of the National Vitamin Foundation for 1949 at the annual meeting of foundation members in New York. Dr. Upjohn succeeds Basil O'Connor, New York, president of the American Red Cross, who was named to the newly created position of honorary chairman of the Board of Governors. J. Paul Folsom, Lederle Laboratories Division, American Cyanamid Company, New York, was elected board chairman. Dr. Robert S. Goodhart, scientific director, in his annual report revealed that by the end of 1948, the foundation's third year, a total of \$186,633.72 has been appropriated for grants-in-aid for research and educational activities. A total of 30 grants-in-aid have been made to 17 institutions for the support of 23 research projects. During 1948, 7 grants-in-aid were continued and 7 new research projects instituted, according to the report. Among educational activities assisted with grants from the foundation during 1948 were publication of the "Handbook on Clinical Nutrition" of the Food and Nutrition Board of the National Research Council, toward which \$12,000 was contributed, and a grant to Washington University School of Medicine, St. Louis, of \$1,225.42 to defray costs of its Nutrition Symposium. As part of its educational activities, the foundation also spent \$10,312.17 to arrange about 4,500 bookings of the foundation's motion picture "Strange Hunger." The foundation's board of governors was increased to eighteen members. Newly elected members were Mr. W. R. McHargue, E. R. Squibb & Sons, New York, and Dr. Ernest H. Volwiler, Abbott Laboratories, North Chicago, Ill.

FOREIGN

Postgraduate Courses in Vienna.—Postgraduate courses for physicians and surgeons are now being offered at the University of Vienna in Austria, which, for the first time since the war, is opening its postgraduate school for doctors from overseas and is able to provide suitable living accommodations.

Anderson-Berry Medal Award.—A David Anderson-Berry silver-gilt medal, together with a sum of money amounting to about 100 pounds, will be awarded in 1950 by the Royal Society of Edinburgh to the person, who, in the opinion of the Council, has recently produced the best work on the therapeutical effect of roentgen rays on human diseases. Applications for this prize are invited. They may be based on both published and unpublished work and should be accompanied by copies of relevant papers. Applications must be in the hands of the general secretary, Royal Society of Edinburgh, 22 George Street, Edinburgh 2, by March 31, 1950.

Australian Postgraduate Federation.—A federation to be known as the Australian Postgraduate Federation in Medicine has been formed with the object of encouragement and advancement of postgraduate medical education, work and research in Australia. In addition the federation will deal with matters common to more than one postgraduate committee, and particularly with the arrangements for visits of teachers to Australia. The formation of the federation will in no way limit the committee in the exercise of its own independent functions in its own state. The members of the federation are the Melbourne Permanent Post Graduate Committee, the Post-Graduate Committee in Medicine in the University of Sydney, the Post Graduate Committee in Medicine of the University of Adelaide, the Postgraduate Medical Education Committee of the University of Queensland, the Western Australian Post Graduate Committee (British Medical Association) and the Tasmanian Post-Graduate Committee in Medicine. Provision has been made to admit to membership organizations from New Zealand or elsewhere on certain conditions. A president, vice president and an executive committee will be appointed each year and the executive committee will be elected from persons nominated by the postgraduate committee of the state chosen for this purpose by the federation.

Israeli Medical School Opens.—The Hebrew University-Hadassah Medical School, the first medical school to be established in Israel, opened its doors May 17 as a joint undertaking of the Hebrew University and Hadassah, the women's Zionist organization of America. Until security conditions permit continuation of construction on Mt. Scopus, the site of the present 400 bed Rothchild-Hadassah-University Hospital, the school will be housed in four hospital units totaling initially over 300 beds in the city of Jerusalem proper. A class of 50 has been admitted, and a like number will be admitted in April 1950. By 1951 the first regular class will be admitted to the full six year course of instruction, the first two years of which will cover the premedical studies and the last four years the standard American medical course. Nearly \$4,000,000 of the necessary \$5,500,000 needed to complete school building program has been raised.

One of the first visiting professors is Dr. Samuel Standard, New York University College of Medicine-Bellevue Medical Center, who will inaugurate instruction in surgery at the school. Among members of the faculty are Bernhard Zondek, gynecology; A. Feigenbaum, ophthalmology; S. E. Franco, pathologic anatomy; Saul Adler, parasitology, and L. Olitzki, bacteriology.

Marriages

JAMES A. VAUGHN JR., West Palm Beach, Fla., to Dr. Phyllis A. Petersen of Baltimore, in March.

JOHN ROBERT SHELL, Lawrenceville, Va., to Miss Betty Jane Moseley of Lake Charles, La., April 23.

ERNEST RANDOLPH TRICE to Miss Virginia Dorsey Brown, both of Richmond, Va., May 7.

LEE R. SANBORN to Mrs. Hildegard Tropp Wolf, both of Angola, N. Y., February 14.

WILLIAM BERNARD YEGGE to Miss Marion Agnes Fleisch, both of Denver, January 19.

EDWARD C. RAFFENSPERGER to Dr. Mary Ames both of Harrisburg, Pa., April 9.

JOHN J. LITZ, New York, to Miss Carolyn Weir of San Francisco, in April.

Deaths

Charles Wesley Adams, Franklin, N. H.; Boston University School of Medicine, 1884; member of the American Medical Association; on the staff of the Franklin (N. H.) Hospital and Memorial Hospital in Concord; formerly mayor; bank president; died March 12, aged 85, of heart failure.

Thomas John Barb * Roby, Texas; University of Oklahoma School of Medicine, Oklahoma City, 1921; on the staff of the Fisher County Memorial Hospital, where he died February 24, aged 61, of pneumonia.

Karl Mikael Beck * Waukegan, Ill.; Loyola University School of Medicine, Chicago, 1918; formerly county physician and superintendent of Lake County General Hospital; died March 19, aged 55.

Nathan Berger * New York; Long Island College Hospital, Brooklyn, 1917; on the staff of the New York Eye and Ear Infirmary; died February 12, aged 56, of carcinoma of the stomach.

Kenneth Edwin Blair * Detroit; Northwestern University Medical School, Chicago, 1938; on the staffs of Grace and Holy Cross hospitals; died February 28, aged 38.

John Blake, Detroit; Detroit College of Medicine, 1907; died March 15, aged 66, of carcinoma of the colon.

William Floyd Boze, Carthage, Tenn.; University of Tennessee Medical Department, Nashville, 1892; for many years county health officer; died March 11, aged 79.

Joseph Bernard Brain * Isabella, Pa.; University of Pittsburgh School of Medicine, 1927; served overseas during World War II; died in the U. S. Veterans Administration Hospital, Aspinwall, March 19, aged 45, of coronary thrombosis.

William Norwood Breckinridge, Fincastle, Va.; University of the South Medical Department, Sewanee, Tenn., 1904; member of the American Medical Association; served during the Spanish-American War and World War I; for many years county coroner and mayor of Fincastle; died March 21, aged 73, of angina pectoris.

Wallace McMurray Burroughs, St. Charles, Ill.; Northwestern University Medical School, Chicago, 1893; member of the American Medical Association; died March 25, aged 78, of chronic myocardial degeneration.

Lewis Angus Wood Burch * Phoenix, Ariz.; Rush Medical College, Chicago, 1897; member of the American Society of Anesthetists; died recently, aged 73.

J. Willard Caldwell, Steamboat Rock, Iowa; St. Louis College of Physicians and Surgeons, 1901; served during World War I; died March 24, aged 68.

Harry Edward Castle, San Francisco; Rush Medical College, Chicago, 1905; died March 29, aged 74, of hypertensive cardiovascular disease.

Burt Thomas Church * North Hollywood, Calif.; University of Nebraska College of Medicine, Omaha, 1923; died March 12, aged 50.

George Henry Cottral * Savanna, Ill.; Marion-Sims-Beaumont Medical College, 1903; served during World War I; died in the Kahler Hospital, Rochester, Minn., March 16, aged 73, of carcinoma of colon.

Samuel Wright Crittenden, Wakefield, Mass.; Dartmouth Medical School, Hanover, N. H., 1898; Medical School of Maine, Portland, 1898; member of the American Medical Association; formerly medical officer in charge of the U. S. Veterans Hospital and on the staff of State Hospital in Boston; died March 26, aged 91, of cerebral hemorrhage and arteriosclerosis.

Stanton Curry * Peekskill, N. Y.; New York University, University and Bellevue Hospital Medical College, 1898; an Associate Fellow of the American Medical Association; on the staff of Peekskill Hospital; bank president; died March 26, aged 79, of lymphatic leukemia.

James Bayard Gregg Custis * Washington, D. C.; New York Homeopathic Medical College and Hospital, New York, 1907; served during World War I; on the staff of the National Homeopathic Hospital; for many years affiliated with Florence Crittenton Home; died February 28, aged 66, of coronary occlusion.

Fred Beam Cyphers, Duncan, Neb.; Lincoln (Neb.) Medical College, 1905; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; member of the American Medical Association; affiliated with St. Mary's and Lutheran hospitals in Columbus; died in the Mayo Clinic, Rochester, Minn., March 22, aged 65, of carcinoma.

Robert Anthony Davis, Ludington, Mich.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; served on the staffs of the Woman's and Providence hospitals in Detroit and the Paulina Stearns Hospital; died March 29, aged 84.

William Earl Dawson, Hookerton, N. C.; Jefferson Medical College of Philadelphia, 1920; member of the American Medical Association; died recently in Raleigh, aged 54, of coronary thrombosis.

George Valentine Dorsheimer * Dewey, Okla.; University Medical College of Kansas City, Mo., 1913; on the staff of the Memorial Hospital, Bartlesville, where he died March 16, aged 73, of carcinoma.

Robert Lee Dossett, Tullahoma, Tenn.; University of Tennessee Medical Department, Nashville, 1908; mayor; served as state senator; for many years city health officer; member of the Coffee County Court; died in the Gartly-Ramsay Hospital, Memphis, March 27, aged 68, of pneumonia, following a broken hip received in a fall.

John Frederick A. Drew, Portland, Ore.; Northwestern University Medical School, Chicago, 1896; died March 13, aged 82, of cerebral hemorrhage.

Thomas Nelson Duncan, Onaway, Mich.; St. Louis University School of Medicine, 1903; died in Cheboygan March 6, aged 71.

Roland Jordan Dunn * Chicago; Rush Medical College, Chicago, 1897; on the staffs of St. Anne's and Bethany hospitals; died March 10, aged 73, of cerebral thrombosis.

Elling H. Ellingsen, Calmar, Iowa; Bennett College of Eclectic Medicine and Surgery, Chicago, 1898; died March 12, aged 87, of hypostatic pneumonia and arteriosclerotic heart disease.

Samuel Henry Freeman, Nashville, Tenn.; Meharry Medical College, Nashville, 1928; professor of anatomy and surgery (orthopedic) at his alma mater; chief physician and head of the health department of Tennessee A. & I. State College; affiliated with Hubbard Hospital; died March 24, aged 50, of coronary heart disease.

Rolland Edward Gardner, Reynoldsburg, Ohio; University of Louisville (Ky.) School of Medicine, 1929; member of the American Medical Association; died March 24, aged 47, of coronary thrombosis.

Edgar James Gilray, Cuba, N. Y.; University of Buffalo School of Medicine, 1891; member of the American Medical Association; formerly medical superintendent of Erie County Hospital in Buffalo; died in Cuba Memorial Hospital March 27, aged 82, of arteriosclerosis.

George Spaulding Greene, Dowagiac, Mich.; Detroit College of Medicine, 1897; member of the American Medical Association; served during World War I; formerly practiced in Gary, Ind., where he was on the staff of Mercy Hospital; died in Pawating Hospital, Niles, March 22, aged 73, of cerebral hemorrhage.

James Anthony Guilfoil * San Francisco; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1911; served during World War I; affiliated with St. Francis Hospital and Southern Pacific Hospital, where he died March 7, aged 61, of coronary occlusion and arteriosclerotic hypertensive heart disease.

Joseph A. Haluska * Detroit; Magyar Királyi Pázmány Petrus Tudományegyetem Orvosi Fakultása, Budapest, Hungary, 1923; served on the city planning commission; on the staff of St. Joseph's Hospital, where he died March 12, aged 49, of pulmonary emboli and portal cirrhosis.

Benjamin Charles Hamilton Sr., Jefferson, Iowa; College of Physicians and Surgeons, Keokuk, 1882; member of the American Medical Association; died March 20, aged 89.

Charles Carter Hamilton * Philadelphia; State University of Iowa College of Medicine, Iowa City, 1923; specialist certified by the American Board of Radiology; member of the New England Roentgen Ray Society; on the staff of Chestnut Hill Hospital; died in the University of Pennsylvania Hospital March 28, aged 51, of bronchopneumonia.

Bell DeVan Hansell * Okolona, Miss.; College of Physicians and Surgeons, Memphis, Tenn., 1911; formerly medical director and owner of a hospital bearing his name; died March 7, aged 61.

Charles Herbert Haskins, Saranac Lake, N. Y.; Yale University School of Medicine, New Haven, 1923; served during World War I; accidentally drowned recently, aged 53.

Bernard N. Hatcher, Baltimore; University of West Tennessee College of Medicine and Surgery, Memphis, 1914; died in Provident Hospital recently, aged 58, of hypertensive cardiovascular renal disease.

Robert J. Heavenridge, Hannibal, Mo.; Central Medical College, St. Joseph, Mo., 1897; died in March, aged 76.

Jeannette Potter Himmelsbach, Buffalo; University of Buffalo School of Medicine, 1890; died March 12, aged 81, of cerebral thrombosis.

Joseph Howerton Hopper, Willisburg, Ky.; Hospital College of Medicine, Louisville, 1898; member of the American Medical Association; died February 3, aged 72, of organic heart disease.

Harold Lee Hurley Ⓢ Jackson, Mich.; Detroit College of Medicine, 1913; past president of the Jackson County Medical Society; fellow of the American College of Surgeons; served during World War I; on the staffs of the W. A. Foote Memorial and Mercy hospitals; died March 11, aged 58, of cardiac failure.

Dennis Bliss Jarrell, Beckley, W. Va.; College of Physicians and Surgeons, Baltimore, 1915; member of the American Medical Association; served overseas during World War I; on the staff of Raleigh General Hospital; died March 30, aged 62, of primary spinal atrophy.

Francis H. Jenkins, Italy, Texas; Chattanooga (Tenn.) Medical College, 1902; died in Columbus, Ohio, March 9, aged 75.

Arthur Henry N. Juengel, St. Louis; St. Louis University School of Medicine, 1908; died March 8, aged 66, of heart disease.

Edmond Norbert Landry, New Iberia, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1911; member of the American Medical Association; for many years parish coroner; on the staff of the New Iberia General Hospital; died March 19, aged 62, of coronary thrombosis.

Isaac Newton Lear, Vandergrift, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1896; died March 18, aged 82, of carcinoma of the prostate.

Carlton George Lee, Highland Falls, N. Y.; University of Alberta Faculty of Medicine, Edmonton, Alberta, Canada, 1925; member of the American Medical Association; served in the Canadian Air Force during World War I; served during World War II; died in the Veterans Administration Hospital, Castle Point, March 25, aged 57, of amyloidosis of the kidney, liver and spleen.

Edwin Lewis, Claremore, Okla.; Central Medical College of St. Joseph, Mo., 1903; died in February, aged 86.

Samuel Lichtenstein, Kecoughton, Va.; University of Georgia Medical Department, Augusta, 1912; died February 21, aged 57.

James Hugh McClelland, Livermore, Calif.; Cooper Medical College, San Francisco, 1912; died in the Veterans Administration Hospital December 18, aged 60.

Crawford Ward McCormick, Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1913; member of the American Medical Association; on the staff of Delray General Hospital; died March 24, aged 60, of coronary occlusion.

William Raymond McDannell, Los Angeles; the Hahnemann Medical College and Hospital, Chicago, 1905; died March 16, aged 74, of hypertensive heart disease.

Samuel James McDonald, Newton, Mass.; Harvard Medical School, Boston, 1901; member of the New England Ophthalmological Society; served as an examiner for the draft board during World Wars I and II; for many years affiliated with St. Elizabeth's Hospital and the Massachusetts Charity Eye and Ear Infirmary in Boston; died March 28, aged 74, of cerebral thrombosis.

Allister Francis MacDougall Jr., Stillwater, Okla.; Boston University School of Medicine, 1944; certified by the National Board of Medical Examiners; served during World War II; died March 14, aged 28.

George McIntyre, East Saugatuck, Mich.; Illinois Medical College, Chicago, 1904; also a graduate in pharmacy; served during the Spanish-American War and World War I; at one time practiced in Chicago, where he was medical inspector for the board of health and affiliated with Ravenswood and St. Elizabeth's hospitals; died March 30, aged 75, of myocarditis.

Edwin Everett Madden, Forest Park, Ill.; Reliance Medical College, Chicago, 1909; died in March, aged 72.

Jesse Krekore Marden, Claremont, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1898; formerly a missionary in Turkey and Greece; died recently, aged 76.

Henry Louis Martin, Detroit; Detroit College of Medicine and Surgery, 1922; on the staffs of Providence Hospital and Holy Cross Hospital; died March 17, aged 58, of coronary occlusion.

Thomas Patrick Martin Ⓢ Carbondale, Pa.; Medico-Chirurgical College of Philadelphia, 1905; served during World War I; fellow of the American College of Surgeons; on the staff of St. Joseph's Hospital; died March 13, aged 71, of acute cardiac failure.

Edward Joseph Meehan, Lowell, Mass.; Jefferson Medical College of Philadelphia, 1947; served a residency at St. John's Hospital; a veteran of World War II; died March 17, aged 26.

Angus Washburn Morrison Ⓢ Wayzata, Minn.; Johns Hopkins University School of Medicine, Baltimore, 1910; formerly on the faculty of the University of Minnesota Medical School, Minneapolis; served during World War I; member of the American Psychiatric Association and the Central Neuropsychiatric Association; for many years on the staff of the Minneapolis General Hospital; died in Eitel Hospital, Minneapolis, recently, aged 65, of carcinoma of lung.

Charles Robert Nelson, Oakland, Calif.; Western Pennsylvania Medical College, Pittsburgh, 1895; member of the American Medical Association; on the staff of the Samuel Merritt Hospital; died February 27, aged 77, of arteriosclerosis and coronary occlusion.

William Henry Nix, Worthington, Pa.; Jefferson Medical College of Philadelphia, 1905; member of the American Medical Association; died recently, aged 73, of hypertension and coronary artery disease.

James Jarvis Parker Ⓢ Elizabeth City, N. C.; Temple University School of Medicine, Philadelphia, 1939; on the staff of Albemarle Hospital; died March 27, aged 34, of coronary thrombosis.

George Floyd Phelps, Drexel Hill, Pa.; Jefferson Medical College of Philadelphia, 1907; served on the staffs of the Jefferson and Philadelphia General hospitals in Philadelphia, New Jersey State Hospital in Trenton, and the Pennhurst State School in Spring City; died March 10, aged 78, of hypertensive cardiovascular disease.

Minor Wallace Pitts Ⓢ Luling, Texas; American Medical College, St. Louis, 1893; past president of the Caldwell County Medical Society; on the staff of the Luling Hospital; died March 20, aged 80, of coronary occlusion.

Clarence Virgil Porterfield, St. Clairsville, Ohio; Starling-Ohio Medical College, Columbus, 1913; president of the county board of health; member of the board of education; died March 17, aged 61, of pulmonary embolism.

Harry Blackburn Pryor, Ashland, Mo.; University of Louisville (Ky.) Medical Department, 1911; member of the American Medical Association; served overseas during World War I; died in March, aged 61.

Gail Kelvin Riddelsperger Ⓢ Warren, Pa.; University of Buffalo School of Medicine, 1933; fellow of the American College of Surgeons; on the staff of Warren General Hospital; died March 15, aged 44.

Mary Caroline Reed Stratton, Denver; Northwestern University Woman's Medical School, Chicago, 1892; died March 19, aged 80, of coronary thrombosis.

George Ross Taylor Ⓢ Akron, Ohio; Western Reserve University School of Medicine, Cleveland, 1924; member of the Summit County Board of Health; served on the staffs of the Wadsworth (Ohio) Hospital and the Citizens Hospital, Barberton; died February 6, aged 50, of coronary occlusion.

Thomas H. Turner, Auburn, Ky.; University of Tennessee Medical Department, Nashville, 1893; member of the American Medical Association; died in Princeton, Ind., March 18, aged 81.

Rufus Whitis Ⓢ Dallas, Texas; Jefferson Medical College of Philadelphia, 1884; died February 22, aged 89.

Leslie Arno Yaeger Ⓢ Trenton, N. J.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1921; served during World War I and World War II; school physician; affiliated with St. Francis Hospital, where he died February 28, aged 56, of hepatitis.

Louis Augustus Zerega di Zerega, Staten Island, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1889; died in Staten Island Hospital March 15, aged 84.

ANKARA, April 19, 1949.

Treatment of Toxic Diffuse Goiter with Thiouracil and Methylthiouracil

Dr. Huseyin Salor of the Istanbul-Pera Municipal Hospital has published observations on 6 patients treated with thiouracil and methylthiouracil. The patients were between 28 and 42 years of age; 4 were women and 2 were men. All were suffering from thyrotoxicosis. The treatment was divided into two periods. During the first period the patients were given a daily dose of 0.30 to 0.40 Gm. thiouracil and 0.20 to 0.25 Gm. methylthiouracil for an average of two weeks. By this time the basal metabolism of all 6 patients and the cholesterol of the blood had become normal again. The feeling of oppression and other hyperthyroid symptoms had disappeared. This treatment had no effect on exophthalmia. Frequent blood examinations and leukocyte counts revealed no abnormalities. During the second period the patients were given a daily dose of 0.15 to 0.20 Gm. thiouracil and 0.05 to 0.10 Gm. methylthiouracil. This dosage was continued for two to three months. In 2 of the 6 patients symptoms of relapse appeared, and they were given another two weeks' treatment. Toxemia or idiosyncrasy symptoms were absent. The patients have been discharged and are being followed up to find out whether it will be necessary to repeat the treatment from time to time.

Fiftieth Anniversary of the Gülhane Hospital

The Gülhane Hospital at Istanbul-Sarayburnu was established in 1898 by Dr. Rieder Pasha. The medical students graduating from the Military Academy Medical School with the rank of captain were required to attend there a one year theoretic and practical course followed by another examination. Drawing lots, they were then assigned to their respective positions. Those having passed the examination with the highest marks were retained at the academy as assistants and instructors. The Gülhane Hospital, which has always held a high place in the esteem of the Istanbul population, continued to function there until 1939, when it was transferred to Ankara. Several of the clinics of this 500 bed hospital now serve as teaching units of the Ankara University medical school.

On the occasion of the fiftieth anniversary of the hospital a ceremony was held on Dec. 30, 1948. It was attended by Ismet İnönü, President of Turkey; Dr. Kemal Bayazit, the Minister of Health and Social Assistance; the Minister of National Defense and other cabinet members, prominent army and civilian members of the medical profession.

Custom-Free Drugs

The bill introduced by the Ministry of Health and Social Assistance proposing the custom-free importation of vital remedies and chemicals has passed the National Assembly and became law. Streptomycin, insulin and the like, the high price of which (5 to 7 Turkish pounds per gram in the pharmacies) often was prohibitive, will now be available for 2.8 to 3 liras—about \$11—per gram. In many cases of tuberculous meningitis treatment with streptomycin had to be abandoned because parents could not afford to pay the high price and the hospital did not have sufficient funds to provide the drug free. The rising cost of living during and after the war has greatly increased the number of tuberculous patients. This reduction in price will enable government hospitals to provide these

important remedies free of charge for patients unable to pay for them. The new law also provides for custom-free importation and tax exemption for DDT, which has proved effective in malaria control work. Though in 1948 there have been no malaria epidemics, the malaria morbidity rate was greatly reduced in the malaria areas and there have been no deaths there due to malaria. The new law also contains a provision for customs and tax exemption for vitally important remedies that may be discovered in the future.

Death of Prof. Akil Muhtar Özden

Prof. Akil Muhtar Özden, who for thirty-seven years taught at the Istanbul University Medical School, died March 12 after a long illness. Like many medical students and physicians who, under the autocratic rule of Sultan Abdul Hamid II, had to leave the country because of their leanings toward democracy, Akil Muhtar, while still an undergraduate at the military medical school, fled to Switzerland, where he continued his medical studies and was graduated from Geneva University. After the declaration of the constitution in 1908 Dr. Akil Muhtar returned to Istanbul to become professor of hygiene at the Istanbul Civil Medical School; in 1909 he became professor of pharmacodynamics and clinical therapy of the Istanbul University Medical Faculty. He had one hundred and fifty-six publications in the Turkish and one hundred and two in the French language to his credit. He was a member of seven foreign medical societies. Prof. Akil Muhtar for many years served as vice president of the Turkish Red Crescent Society and took part in the international Red Cross Congress. His textbooks on pharmacodynamics and those on treatment have had a great many editions. At his Istanbul consulting rooms he was the most sought after authority on internal diseases; he was also advisory physician to President Ismet İnönü.

ISRAEL

(From Our Regular Correspondent)

JERUSALEM, April 22, 1949.

Medical Faculty of the Hebrew University in Jerusalem

The Medical Faculty of the Hebrew University in Jerusalem will be established soon. It has grown from the Institute of Microbiology, which was provided by the American Jewish Physicians' Committee and which was functioning before the University was opened in 1925. Other departments eventually were created, until there were available all courses necessary for premedical studies.

In 1936 the University and the Hadassah Zionist Organization of America agreed to undertake the establishment of a medical faculty in the Hebrew University. The Hadassah was to provide a modern hospital and facilities for teaching clinical subjects, and the University the preclinical education. The hospital now is known as the Hadassah-Rothschild University Hospital. Senior clinical appointments were to be made after consultation between Hadassah and the university, who were to be advised by a board of American authorities eminent in medical education.

Some of the preclinical departments are in need of expansion, and plans for enlargement were undertaken before the outbreak of recent hostilities. While some building was undertaken during hostilities, the preclinical departments still in need of expansion are bacteriology and hygiene, parasitology, physiology and pathologic chemistry, experimental pathology and cancer research, and radiobiology.

The hospital beds were to be increased from 300 to 500, and a hospital for tuberculosis for teaching was to be erected,

but this building program also was interrupted. Eventually the school will provide a six year course, of which two years will be devoted to premedical subjects. A year of internship will be obligatory. About 50 students will be admitted each year to the school. In time a dental faculty and a college of pharmacy will be added to the school.

Because of the shortage of scientific personnel, the personnel of the medical school will be recruited in part from persons in Israel and abroad and from younger members of the staff who will be sent to the United States for further training. A number of the latter already have been sent to the United States. In spite of the handicaps, the university has had considerable teaching experience. Many of its graduates hold responsible governmental and civilian positions. Furthermore, many have received postgraduate clinical training.

The Jerusalem Society for Internal Medicine

A Society for Internal Medicine was founded in Jerusalem in March 1949. This society was formed as a result of a proposal made at the International Congress for Internal Medicine held in Basel in September 1948. At the Basel meeting it was suggested that an international organization of the societies for internal medicine be formed.

ITALY

(From Our Regular Correspondent)

FLORENCE, April 15, 1949.

Course on International Medical Ethics

The Surgeon General of the Belgian Army, Dr. J. Voncken, Secretary General of the International Committee on Military Medicine and Pharmacy, presented four lectures on international medical ethics at the School of Military Health in Florence. General Voncken discussed military medicine at the national and international levels, the history of the humanitarian movement and the international judicial situation of the physician. The chancellor of the University of Florence has invited General Voncken to hold an analogous course at the University of Florence next fall.

Oto-Neuro-Ophthalmologic Association

This association held its fourth international congress in Bologna. Meningoendocraniosis in ophthalmology was the subject of the first report presented by Professor Rubino of Florence. The speaker gave a brief summary of the general symptoms, such as headache, and endocrinodiencephalic, mental, olfactory and cochleovestibular disturbances. He discussed the various fundamental roentgenologic signs of the cranium and the ocular signs and symptoms which may be encountered in meningoendocraniosis. The lesion of the ocular fundus may involve the optic papilla and the central retinal vessels. There may be such functional symptoms as bitemporal hemianopsia referable to the upper quadrants, also called "chiasmal sign" or "small chiasmal syndrome," which may be of great localizing value in diagnosis.

Professor Bertolotti of Naples discussed the relationship between endocraniosis and deep perisunitis.

Professor Porta of Siena discussed pontocerebellar arachnoiditis and meningoendocraniosis of the temporobasilar region; he stated that when this condition is secondary to chronic inflammatory processes of the mastoid it may induce symptoms which justify a parallelism with the forms described by Lunedei as sequelae of hyperergic chronic inflammatory processes at the base of the cranium, involving also the diencephalon.

The reports were followed by discussion in which many in attendance participated.

BRAZIL

(From Our Regular Correspondent)

RIO DE JANEIRO, April 27, 1949.

Virus of Brazilian Typhus in Milk

Dr. Octavio de Magalhães, of the Oswaldo Cruz Institute, was able to prove, as has been reported in previous letters, that the virus of Brazilian typhus can pass through the placenta of *Macacus rhesus* and infect the fetus, and can go through the apparently normal mucosa of the gastrointestinal tract of dogs causing the disease. Recently, Dr. de Magalhães was also able to demonstrate the presence of the virus in the milk of goats (*Capra hircus*), these animals being, as the same author pointed out in the past after careful experimentation, a very good reservoir of the Brazilian virus, as shown by the presence of the virus in blood and by a positive group Weil-Felix reaction of high titer, although without apparent disease. In many places of the interior of Brazil goats are a substitute for cows as a milk supply for children and adults, and in some districts goat's milk is even considered superior to cow's milk. Now, with the demonstration that the virus of Brazilian typhus may be present in goat's milk, and the proof that the virus is able to pass through the apparently normal digestive tract, it is easy to understand how infants living in strictly domestic environment can contract the disease, as Dr. de Magalhães has shown in several instances, even for very young infants.

Blood Types of Brazilian Indians

Dr. Ernani M. da Silva, of the Oswaldo Cruz Institute, and Drs. F. Ottensooser and R. Pasqualin, of the Laboratório Paulista de Biologia, studied the blood of Caiuá and Bororo Indians of the state of Matto Grosso for the determination of the common blood groups, MN factors and Rh types. The blood of 356 Indians (237 Caiuás and 119 Bororos) revealed the O group in all of them. Among 134 Caiuás 79.9 per cent belonged to type M, 0.7 per cent to N and 19.4 per cent to MN. Among 173 Caiuás and 103 Bororos not even one negative Rh was found. The distribution of the Rh types in 135 Caiuás and 103 Bororos was almost identical: the average values were 22.7 per cent Rh₁, 19.3 per cent Rh₂, and 58.0 per cent Rh₁Rh₂ or Rh₃. American Indians are connected with Mongoloids by some serologic characteristics, such as an appreciable ratio of R₂ and scarcity or lack of the Rh-negative type, but generally they also are distinguished within this ethnical group by high proportions of O, M and Rh₂. In Matto Grosso Indians these percentages are particularly high.

A Focus of Echinococcosis

After Iceland—the place where the incidence of hydatidosis is highest—Australia, Argentina and Uruguay are known as important foci of the disease, which is connected with cattle raising, abundance of dogs and poor habits of personal hygiene. Evidence is accumulating to prove that the state of Rio Grande do Sul, the southernmost of Brazil and adjoining Uruguay, and also devoted to cattle raising, is another focus that must be taken into consideration. Dr. Darcy Xavier, of the Misericórdia Hospital of Pelotas, a city of 80,000 population near the Uruguayan border, studied the records of the hospital, from 1918 to 1947, to find out the number of cases of hydatidosis attended at that institution and gather data about the patients and the disease. During the thirty year period, 196 cases of the disease were treated at the hospital, all the patients being residents of the rural districts around Pelotas, the present aggregate population of which is about 500,000. On the basis of this population at the midpoint of the period, this represents the average annual morbidity rate of 1.53 per hundred thousand. As would be

expected, the incidence varies with the individual districts: Arroio Grande 5.7, Pinheiro Machado 5.3, Piratiny 5.0, Pelotas 2.2, Palmar 2.1, Herval 1.7, Cangussú 1.0 and Jaguarão 0.8. The cases are almost evenly divided between the two sexes: 90 cases in males (45.9 per cent), and 106 in females (54.1 per cent). The age distribution of the patients was as follows: 0 to 9 years, 26 (13.3 per cent); 10 to 19 years, 54 (27.5 per cent); 20 to 29 years, 55 (28.1 per cent); 30 to 39 years, 33 (16.8 per cent); 40 to 49 years, 16 (8.2 per cent); 50 to 59 years, 9 (4.6 per cent); 60 to 69 years, 2 (1.0 per cent), and 70 to 79 years, 1 (0.5 per cent). The localization of the cysts was as follows: liver, 102 (52.0 per cent); lungs, 43 (21.9 per cent); diffuse abdominal form, 16 (8.2 per cent); orbit, 5 (2.5 per cent); muscles, 4 (2.0 per cent); retroperitoneal, kidney, mesentery and epiploon, 3 each (1.5 per cent each); pancreas, mammary gland and bladder, 2 each, ligamentum latum uteri, pleura, ductus choledochus, ovary, spleen, parotid mediastinum and iliac bone, 1 each.

Correspondence

HEALTH TEACHING BY PHYSICIANS

To the Editor:—One of the objectives of the American Medical Association which has been stressed a great deal lately is public health education. What may be a doctor's role in such a program? One of the finest avenues open is health teaching in a college or university. Our belated interest in public relations can receive impetus from this contact with the public, teaching hundreds of impressionable young students in a wholesome atmosphere away from the sickroom and office. Such an experience will be pleasurable and beneficial to all concerned.

There are many fields of health taught in a university in which the knowledge of the physician is invaluable. At the University of Utah last year, three thousand students in a student body of ten thousand took courses in health. Except for a few hundred in the field of school health education, all these students were taught by busy practicing physicians. It is with the idea in mind that a physician has an excellent opportunity to be of service to the public and to his profession that an outline of our major courses at the University of Utah is offered.

For forty years a course in personal hygiene has been required of all men and women at the University. Sections on personal hygiene are taught by physicians who spare the time year after year to come to the campus and teach. Occasionally the time is a costly sacrifice; nevertheless, these men and women have compensations beyond the honorarium offered. They value their university associations; above that, they feel that the contact with young people and the information given are worth while. Obviously, such information does not remain restricted to the student himself but is disseminated in ever widening circles to family, friends and community. At present, four men physicians and one woman physician are teaching about 1,300 men and women personal hygiene.

As a result of the furor raised about the physical defects found in recent selective military training health examinations, there is a strong tendency to require courses in personal hygiene in the higher institutions. This is an opportunity for physicians.

At the University of Utah another health course is unique and has commanded wide attention. It is labeled "Matrology," a word coined from the combination of "mater" and "ology"; i. e., science of motherhood. It was started soon after World War I by a busy practitioner in Salt Lake City who felt that "university women should know more than factory women" about their bodies during oncoming motherhood. He taught

them "what a doctor would like his daughter to know." Enrollment grew with the years and was limited to women until a demand from the men resulted in the establishment of "Patrology" in the spring of 1947.

Matrology and Patrology fill a popular demand and need. They are similar courses in obstetrics and pediatrics which stress the normal. Two thirds of the course is devoted to prenatal care, to human embryology, to common disturbances and complications of pregnancy and to the mechanics of normal labor. The film "Normal Labor" taken by De Lee at Chicago Lying-in Hospital climaxes this part of the course. The latter part is concerned with infant care in the first year. Matrology and Patrology are not required courses. Registration is entirely voluntary; yet 338 women and 815 men were enrolled last year—11½ per cent of the student body in one year.

These courses are taught by physicians, who not infrequently come directly from the delivery room to the lecture room. Their voices carry authority.

Evaluations of Matrology and Patrology are enthusiastic, from the students, parents, physicians and the University administration. Students who later become parents find the subject matter of inestimable value in allaying fears and preparing for parenthood. Boys and men particularly have been slighted in this field. Local physicians have been particularly impressed with the intelligence and cooperation of their women patients who have had Matrology. Comments are being made already on the cooperation and participation of the prospective fathers in conferences with the physician before and after birth of their babies. It is apparent that such courses in a university promote a good rapport between the medical profession and a very fine portion of our population.

Another course of value is entitled "interpretation of medical nomenclature." It is taken by those who plan to be in close association with the medical profession and with hospitals. These include student dietitians, physical therapists and social workers. A closely related course is that on "Medical Information for Social Workers." These subjects are taught by physicians.

Physicians from Salt Lake City have been most generous in devoting their time and knowledge to the academic field at the University. They are guest lecturers in courses in the areas of physical therapy, first aid and safety, school health education, preparation of health teachers, child development, mental hygiene, public health, courtship and marriage. The areas are wide into which physicians may enter.

Heretofore, too much health teaching has been left to poorly trained personnel. Physicians are always welcome in the health education field. More active and aggressive participation is recommended.

ALMA NEMIR, M.D., Salt Lake City.

ROENTGEN IRRADIATION FOR THYROTOXICOSIS

To the Editor:—The article in your April 16 issue by Robert H. Williams on selection of therapy for individual patients with thyrotoxicosis fails to accord roentgen irradiation the place it has established in the treatment of this disease.

The author's point that initial treatment with thiouracil is applicable in many cases is well taken. His frank comments on the complications and bad effects of this drug are to be commended. His impression that irradiation is best given by radioiodine is hardly supported by his statement that "the main drawback of this type of treatment is the difficulty involved in selecting the appropriate dosage, errors in which may either cause myxedema or permit the thyrotoxicity to persist. . . .

Radioiodine is distinctly less available throughout the country than are the other forms of therapy and, in the light of present information, it should remain so. Extensive use of it would pose a number of public health considerations." In view of the frank difficulties of administration and of dosage calculation, it would seem that the simpler and safer method of irradiation by external roentgen rays merited more prominence in the article, effective as it is in over 80 per cent of cases of diffuse toxic goiter. Myxedema is much less common after roentgen irradiation than after radioiodine.

Last, and by no means least, I concur with the author in the merits of thyroidectomy, especially in patients with a large nodular gland and in patients who have failed to respond to thiouracil and irradiation.

Intense attention to certain aspects of any problem commonly results in inattention to others, no matter how well established. The interest in radioactive isotopes in recent years has caused considerable neglect of simpler, safer and more available methods of irradiation.

L. H. GARLAND, M.D., San Francisco.

MEDICAL CARE OF THE INDIANS

To the Editor:—In two recent issues of THE JOURNAL have appeared special articles on the care of Indians in the Upper Midwest area and in the Navajo area. As I am at the present time a doctor in the Indian Service, I read these articles with considerable interest, and as I have worked for the Indian Service in Idaho and consequently know something of conditions in the Upper Midwest area, I am pleased to observe that the group who made that survey did an exceptionally fine piece of work. Both their findings and recommendations show considerable discernment and acumen. I am not familiar with the Navajo area and consequently am in no position to form an opinion of that report. I would be much interested, however, in a report on the area of Washington, Oregon and California, as I do know something of Indian conditions in these states and know that they differ somewhat from those of the Upper Midwest area.

Being a federal employee, I am not at present eligible to belong to a state or county medical society and consequently am not a member of the American Medical Association. Also being on a federal salary I am scarcely able at this time to contribute the entire \$25 toward defeat of the vicious so-called health bill sponsored by Oscar Ewing and others. I am, however, enclosing a check for \$10, which I hope will help a little in defeating this proposed legislation. I know at first hand what federal medicine does to a doctor, and I know what it does to patients.

C. W. DEWEY, M.D., Hoopa, Calif.

FREE ISOTOPES

To the Editor:—Students of the infiltration technic will be pleased at the latest evidence of how even the most erudite will fall for the Grecian gift.

In THE JOURNAL for April 16, page 1084, appears the heading "Expand Free Radioisotope Program." There then follows an explanation that the U. S. Atomic Energy Commission has announced that all isotopes are now free.

However, in the next paragraph it states that to finance the new program for its first year of operation \$450,000 has been allocated. This is just for the first year. Time passes rapidly. Estimates are often inadequate. Is it not unreasonable to envisage that this free program is going to require allocations

of perhaps \$10,000,000 in the next ten years? Since when, then, is it free?!

It is readily granted that this program cannot be conducted or entirely subsidized by private enterprise. The Atomic Energy Commission is doing a good job. However, do not let us deceive ourselves. The radioisotope program is not free; it is expensive; we are all paying for it. May we suggest that you reprint this article and use the heading "Expand Costly Radioisotope Program." "NOTICE: All tax-payers kindly stand ready to pay at least \$500,000 for the first year."

M. A. Sisson, M.D., San Francisco.

AN ALLERGY SURVEY

To the Editor:—The New Jersey Allergy Society has formed a committee on aerobiology to do an air survey of the state of New Jersey for the purpose of finding allergenic factors not presently recognized. The work will be done in the following fields: (1) pollen surveys, (2) bacteria surveys, (3) fungi surveys, (4) chemical contaminants and (5) meteorology.

With funds supplied by Schering Laboratories, six Wells air centrifuges will be set up in widely separated sites in the state. Daily air specimens will be studied. The chairmen for the entire project are Drs. Nathan Schaffer of East Orange, and Edward E. Seidman, of Plainfield. Subchairmen are as follows:

1. Pollen, Dr. L. Byck, Newark.
2. Bacteria, Dr. E. Seidman, Plainfield.
3. Fungi, Dr. N. Schaffer, East Orange.
4. Chemical contaminants, Dr. C. Weston, Glen Ridge.
5. Meteorology, Dr. F. Rosen, Newark.

The subcommittee on mycology, which consists of Drs. Schaffer, Seidman, Byck, Suesserman and Feldman, are attending conferences on mycology four hours a week at Rutgers University in New Brunswick, under the direction of Drs. C. M. Haenseler and B. H. Davis of the department of plant pathology, College of Agriculture. These conferences started with the school term in February, and plans are being made for their indefinite continuance. Drs. Haenseler and Davis will work with this committee in attempting to identify any fungi found in quantity. Extracts of these will be made and sent to all members of the society for clinical testing and evaluation.

Plans are being made to set up similar conferences in bacteriology and pollen identification in the near future.

NATHAN SCHAFER, M.D.,
East Orange, N. J.

IT'S THE F. S. A.

To the Editor:—In regard to a Current Comment, THE JOURNAL, February 19, page 531, in addition to your observation concerning letterheads, you may be interested to know that even lantern slides made and issued by the National Cancer Institute for distribution throughout the United States in the fields of professional and lay education are stamped, at the bottom, so that all can read F. S. A.

In all innocence, during a preview of some of these slides which I saw at the National Cancer Institute, I inquired what F. S. A. meant. I was told it meant "Federal Security Agency," and then I asked why it wasn't N. C. I., National Cancer Institute. The answer was simply "Orders."

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Patient not Personally Liable for Medical Fees.—In two recent cases the Supreme Court of North Carolina had occasion to consider the right of a physician to recover a fee directly from his patient when the patient is injured during the course of his regular employment.

In the case of *Worley v. Pipes* the plaintiff filed suit to recover a sum alleged to be due him from the defendant for medical services rendered following an accidental injury. From a judgment in favor of the plaintiff physician, the defendant appealed to the Supreme Court of North Carolina.

The defendant was injured by an accident arising out of his employment with a motor transport company, which company was subject to the provisions of the state workmen's compensation law. He accordingly went to his family physician, the plaintiff, for medical care and the plaintiff undertook to treat, and did successfully treat, the defendant for his injuries. At the time the medical services were rendered, neither the plaintiff nor the defendant knew that the case was compensable under the workmen's compensation law. The reasonable value of the services rendered by the plaintiff was \$44, and the defendant made a token payment of \$5 and impliedly agreed to pay the balance. Subsequently, the defendant, at his employer's suggestion, filed a claim under the workmen's compensation law and the Industrial Commission awarded him compensation, including the sum of \$13.50 for medical services. When the defendant refused to pay the balance of \$25.50, the present suit was filed.

The workmen's compensation law (General Statutes, section 97-90) provides:

(a) Fees for attorneys and physicians and charges of hospitals for services under this article shall be subject to the approval of the Commission;

(b) Any person (1) who receives any fee, other consideration, or any gratuity on account of services so rendered, unless such consideration gratuity is approved by the Commission or such court, . . . shall be guilty of a misdemeanor, and upon conviction thereof, for each offense, be punished by a fine of not more than \$500.00 or by imprisonment not to exceed one year, or by both such fine and imprisonment.

The defendant therefore contended that he did not owe anything personally because the foregoing section prohibited the payment of any fee not approved by the Industrial Commission. The plaintiff contended that if such is the effect of the foregoing provision then it is unconstitutional as being arbitrary, unreasonable and class legislation.

In addition to payment of compensation for an accidental injury arising out of and in the course of the employment, the workmen's compensation act provides that "medical, surgical, hospital and other treatment . . . shall be provided by the employer." The employer's liability for such medical, surgical, hospital service or other treatment required, when ordered by the Commission, shall, according to the act, be limited to such charges as prevail in the community for similar treatment of injured persons of a like standard of living when such treatment is paid for by the injured person. The act also provides that if the employer and injured employee failed to reach an agreement in regard to compensation, either party may make application to the Industrial Commission for a hearing in regard to the matters at issue and for a ruling therein, upon receipt of which application the Commission shall set a date for, and give notice of hearing. The Commission or any of its members shall then hear the matters at issue, determine the dispute, and make an award. There may be a review of the award by the full Commission, the superior court and the Supreme Court. Thus it is seen, said the Supreme Court, that the General Assembly has prescribed an adequate remedy by which any matter in dispute may be determined and settled.

The plaintiff makes it appear by his pleadings that the parties were subject to the workmen's compensation act and that he

submitted his bill to the Industrial Commission and received approval for less than the full amount. It does not appear, however, that he asked for any hearings before the Commission or that he appealed the Commission's ruling. Under such circumstances, said the Supreme Court, the plaintiff is bound by the provisions of the act. Since the act provides that fees for physicians shall be subject to the approval of the Commission, and makes it a misdemeanor for anyone to receive any fee for services so rendered unless it be approved by the Commission, any promise made by the defendant-employee, to pay plaintiff the balance due on his account, is unenforceable and void. Consequently the trial court erred in finding for the plaintiff and the judgment in his favor was accordingly reversed.

In the case of *Matros v. Owen*, the plaintiff filed suit to recover a sum alleged to be due him from the defendant for medical services rendered following an accidental injury. From a judgment in favor of the plaintiff-physician, the defendant appealed to the Supreme Court of North Carolina.

The defendant was injured by an accident arising out of his employment as a mechanic for a company which was subject to the workmen's compensation law. The employer, thinking the injury was compensable under such law, directed the defendant to go to the plaintiff-physician for medical services. The reasonable value of the services rendered by the plaintiff was \$25 and a bill in this amount was filed with the employer. Subsequently the employer and his insurance carrier denied liability, so the physician filed suit against the patient to recover the fee from him.

In addition to raising the same defense as was raised in *Worley v. Pipes*, the defendant contended that notwithstanding the fact that the employer denied liability and refused to pay for medical treatment required by the defendant he, the defendant, who was not liable for such charges because the statute requires the employer to furnish medical attention even though the defendant was not entitled to compensation for the injury.

It does not appear, said the Supreme Court, that either party applied to the North Carolina Industrial Commission for a hearing in regard to the matter at issue and for a ruling thereon, as provided for in the workmen's compensation act, even though the plaintiff alleged and the court found that the parties were subject to, and had accepted the provisions of, such law. The remedy open to the defendant and to the plaintiff in respect to his bill for services rendered, said the Supreme Court, was to make application to the Industrial Commission and have it consider for approval the plaintiff's bill in the light of the provisions in the act. If the applicant be dissatisfied with the ruling of the Industrial Commission an appeal may be taken pursuant to the provisions therein stated. Under the facts alleged, the defendant is not indebted to the plaintiff for the services rendered, concluded the Supreme Court, and the judgment of the trial court in favor of the plaintiff was therefore reversed. *Worley v. Pipes*, 50 S. E. (2d) 504 (North Carolina, 1948), *Matros v. Owen*, 50 S. E. (2d) 509 (North Carolina, 1948).

Medical Motion Pictures

REVISED EDITION OF MOTION PICTURE REVIEWS NOW AVAILABLE

The Committee on Medical Motion Pictures has completed the first revised edition of the booklet entitled "Reviews of Medical Motion Pictures." It now contains all the film reviews published in *THE JOURNAL*, to Jan. 1, 1949. It also includes a classified table of contents as well as a list of motion pictures available through the Motion Picture Library, American Medical Association.

The purpose of the reviews is to provide a brief description and evaluation of motion pictures which are available to the medical profession. Each film is reviewed by competent authorities.

One copy has been mailed to the secretary of each county and state medical society. Additional copies are available on request from: Committee on Medical Motion Pictures, American Medical Association, 535 North Dearborn Street, Chicago 10.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Alabama State Medical Assn. Journal, Montgomery 18:177-208 (Jan.) 1949

Certain Anatomic Factors Related to Pathogenesis of Hemorrhoids: The Author's "Obliterative Suture" in Treatment of Small and Middle-Sized Internal Hemorrhoids. H. J. Fournier.—p. 156.

Oral Streptomycin as Intestinal Antiseptic.—Lockwood and his associates discuss the conflicting nature of reports on the oral administration of streptomycin in preparation for surgical treatment. They report 24 patients so treated and describe the methods used to obtain serial colony counts on the three groups of organisms studied, the coliform group, the streptococcus and the clostridia. Results obtained were inconsistent. Approximately half of the patients treated showed no response in the coliform group to orally administered streptomycin. About seven eighths of the patients showed no significant reduction in the number of streptococci present in the stool, and nearly two fifths of the cases showed no significant reduction in the number of clostridia present in the stool. Sensitivity titrations on the *Escherichia coli* group showed rapid development of resistance to streptomycin and brought out the fact that many strains of *E. coli* become able to proliferate in the concentrations of streptomycin which exist in feces. In a series of 9 cases in which treatment was with combined streptomycin and phthalylsulfathiazole results were also inconsistent. The authors conclude that the effect of orally administered streptomycin is unpredictable and unreliable, and its use in the preoperative preparation of surgical cases is not to be recommended.

Prognostic Location of Carcinoma of Rectum.—According to Waugh and Kirklin, the determination of truly comparable survival rates in patients undergoing combined abdominoperineal resection, and in those undergoing the other procedures which have arisen to challenge it, is not simple. The histologic grade of the lesion and its extent are factors which must be studied, but the location of the lesion, with respect to its distance from the anal margin, may also be important. The authors studied the effect of the level of the lesion on the prognosis in carcinoma of the rectum and the lower part of the sigmoid colon on 388 cases from the Mayo Clinic. It appeared that those patients whose lesions lie within approximately 5 cm. of the anal margin have a poorer prognosis than those whose lesions lie above this level. In order to obtain a more homogeneous group for analysis, the 248 cases in which the lesions showed grade 2 (Broders) malignancy were analyzed. These data show the same general trend as those of the entire group, but the differences are more clearcut. Patients whose lesions were within 5 cm. of the anal margin had a poorer prognosis than those with lesions lying higher up, and those with lesions lying 6 to 10 cm. removed from the anal margin had a poorer prognosis than those with lesions 11 cm. or more removed from this point. Considering only lesions with nodal involvement, a location 11 cm. or more removed from the anal margin allowed a much more favorable prognosis than did a lower location. The authors consider it unlikely that there is any inherent variation in the malignancy of adenocarcinomas at varying levels of the bowel and suggest that lateral spread beyond the line of resection carried out by the combined abdominoperineal operation is the probable explanation for the inferior prognosis in patients with lesions lying within 6 cm. of the anal margin.

Effect of Growth Hormone on Inorganic Phosphorus Levels in Plasma. Choh Hao Li, I. Geschwind and H. M. Evans.—p. 67.

Effect of Estrogen and Progesterone on Lactation.—Walker and Matthews made observations on the effects of antepartum and postpartum administration of estrogens, of progesterone and of combinations of estrone and progesterone on lactation in intact and in ovariectomized rats, using the growth rate of nursing young to indicate the rate of milk secretion. Daily (200 micrograms) treatment with estrone or diethylstilbestrol dipropionate begun on the second day of lactation does not inhibit milk secretion in ovariectomized rats, while moderate daily (5 micrograms and 10 micrograms) injection of estrone inhibits lactation in intact rats, the inhibition appearing ten to twelve days after the beginning of treatment. The inhibition of lactation induced by treatment with still larger dosage (1 mg.) of diethylstilbestrol dipropionate both in intact and in ovariectomized rats was accompanied by loss of weight of the mother and is interpreted as a toxic effect. Antepartum injection of estrone does not prevent the initiation of lactation either in ovariectomized (25 micrograms) or in intact (25 micrograms and 100 micrograms) rats but does produce a delayed depression in intact animals. Daily treatment with progesterone begun

before (2.5 mg.) or after (5 mg.) parturition neither prevents nor inhibits lactation. Simultaneous injection of estrone and progesterone begun before or after parturition does not prevent lactation but does inhibit established lactation after ten to twelve days of treatment. The proliferation of the mammary glands showing inhibition of lactation suggests that stimulation of mammary growth by combined action of estrone and progesterone plays a role in the inhibition of milk secretion in the rat.

Decortication of Nonexpandable Tuberculous Lung.—Mulvihill and Klopstock reasoned that pulmonary decortication used in the treatment of fibrosing traumatic hemothorax during the war might be applicable to some of the problems of pulmonary tuberculosis. They present the case material on the early results of an attempt to apply the basic principles of pulmonary decortication to postpneumothorax nonexpandable tuberculous lung. The indication for decortication in the first case was obliteration of the pleural dead space resulting from a postpneumothorax nonexpandable lung and its accompanying recurrent effusions. It was hoped that this would avoid a multiple stage deforming thoracoplasty. The result to date has been most satisfactory. In the second patient the object of decortication and reexpansion was to achieve sufficient increase in functional capacity to permit a permanent collapsing operation urgently indicated for cavity closure on the contralateral side. The procedure was successful. In the third patient obliteration of the right pleural space after artificial pneumothorax of fourteen years was achieved. The patient was relieved completely of symptoms of tension and dyspnea and stated that breathing was easier. He was relieved of the necessity of periodic refills and thoracenteses for recurrent fluid. He has been able to work at his profession as a commercial artist. The fourth patient presented a classical indication for decortication of a nonexpandable lung. The tuberculous process seemed to have been arrested for over seven years. The cause of the nonexpandability seemed to be chiefly the constricting fibrous coating of the pleura due to the chronic pneumothorax. The successful surgical reexpansion spared the patient an extensive thoracoplasty. The fifth case in this series represents a failure which was probably due to severe parenchymal fibrosis of the collapsed lung. So far there has been no clinical or roentgen evidence of reopening of cavities or reactivation of tuberculosis in the reexpanded lungs. Pulmonary decortication appears to be a useful procedure for dealing with the postpneumothorax nonexpandable lung.

Strangulation of Stomach and Diaphragmatic Hernia.—Dugan and Samson report 2 cases of traumatic diaphragmatic hernia with acute strangulation of the stomach. In both instances the diagnosis was made preoperatively, surgical treatment was performed transthoracically, the stomach was the only abdominal viscus involved and successful repair was obtained. Both cases occurred in young men in the military service, and occurred after dietary indiscretion. In neither patient had the diagnosis of hernia been made prior to the acute illness. A

review of the literature revealed 4 similar cases with a mortality of 75 per cent. The authors conclude that all traumatic diaphragmatic hernias should be repaired as soon as the diagnosis is made and certainly before signs of obstruction occur. The transthoracic approach is the method of choice in the repair of hernias of this type.

Boric Acid, a Poison.—Fellows and his associates say that in the past two years at the Eastern Maine General Hospital 3 deaths have occurred in which boric acid poisoning had been suspected. In the first case chemical analyses of the tissues obtained at autopsy failed to reveal the presence of boric acid or other compound of boron. In the second case small amounts of boric acid were recovered from the brain and liver. In the third case large amounts of boric acid were recovered from both the brain and liver. Boric acid is ineffective as a bacteriostatic and bacteriocidal agent. The manifestations of boric acid poisoning are erythema of the skin followed by exfoliative dermatitis, exfoliative ileitis, hemorrhagic papillary edema of the bladder mucosa and degenerative changes in the central nervous system. Large doses of boric acid produce a severe state of shock. The authors are of the opinion that boric acid should be recognized as a dangerous poison and eliminated from the Pharmacopoeia.

Ephedrine and Nocturia.—Vickers stresses that in male patients with nocturia caution is necessary in the use of ephedrine. These patients should be forewarned that they should stop this medicine in the event of an increase in nocturia. The author cites several cases to illustrate this; when the ephedrine was withdrawn from these patients their nocturia returned to its previous status.

Aqueous Penicillin at Twelve Hour Intervals in Pneumonia.—Tumulty and Zubrod report observations on patients with pneumococcal lobar pneumonia. Among these were 79 who were treated with aqueous penicillin G solution given intramuscularly every twelve hours, 69 received aqueous solution of penicillin intramuscularly every three hours and 58 were given penicillin in oil and beeswax. The patients who were treated with aqueous penicillin G solution, 300,000 units intramuscularly every twelve hours, fared as well as those on the usual schedules of administration. The authors regard the intramuscular administration of 300,000 units of aqueous penicillin G solution every twelve hours as the treatment of choice for pneumococcal lobar pneumonia.

Testosterone in Treatment of Depressions.—Altschule and Tillotson say that the injection of testosterone has been known to cause remission in male patients with depressions. The rationale for this treatment in the past has been that of

a replacement therapy in men past middle life. The fact that small doses are ineffective should have suggested the inadequacy of this concept. Some of the effects of the injection of steroid hormones resemble those caused by electroconvulsive therapy; these include fall in the plasma protein level, decrease in lymphocytes, reduction in eosinophil count, increased diuretic response to water and evidence of extracellular retention of water and sodium. The administration of desoxycorticosterone and of progesterone having failed to cause remission of mental symptoms, it was decided to use testosterone; all three of the hormones mentioned have the effect of causing salt and water retention, but only the last has an additional marked anabolic action. Thirty-one patients with the depressed phase of the manic-depressive psychosis, with involutional psychoses with depression, with reactive depressions and, in 1 case, schizophrenia with a strong depressive component were given testosterone intramuscularly in doses of 50 mg. daily for two or three weeks. The administration of testosterone in large doses was followed by remission of mental symptoms in all types of depression. The hormone acts apparently not as a specific sex hormone but as a substance with strong anabolic effects. In some patients the effects of electroshock and of testosterone are interchangeable, a phenomenon that suggests that the favorable effects of electroshock therapy are reparative and not destructive.

- Tuberculous Fistula. L. S. Knapp.—p. 73.

Treatment of Respiratory Diseases.—Kinghorn and his co-workers administered autogenous bacterial filtrates and vaccines to 47 patients with various chronic respiratory conditions. Twenty-three of these patients had lung disease and 24 had chronic nasal and accessory sinus troubles. Of the 23 patients with lung disease, 1 had bronchiectasis, 2 had chronic allergic bronchitis and 20 had far-advanced pulmonary tuberculosis. The patients were given the vaccines and bacterial filtrates intracutaneously into the forearm, vaccine into one arm and bacterial filtrate into the other, and with each successive dose alternating from one to the other arm. The injections should begin with small doses, 0.05 cc. of both bacterial filtrate and vaccine, and each week the doses can be increased by 0.05 cc. until 1 cc. of each preparation is reached. The first dose of 0.05 cc. vaccine should contain approximately 200,000,000 organisms. Injections should be given once a week, and treatment continued from four to six months. To the patients with chronic sinus diseases the bacterial filtrate solutions were also put directly into the sinuses when necessary and were always applied directly on swabs into the middle nares. The patient with bronchiectasis did not improve. The 2 patients with chronic allergic bronchitis improved, and 6 of the 20 patients with far-advanced pulmonary tuberculosis improved. Of the 16 patients with sinus disease, 6 were cured, 13 were improved or cured and 3 were failures. All the 8 patients with chronic nasal catarrh were improved and 3 of them were cured. *Staphylococcus aureus* was present in all 24 patients with sinus diseases and chronic nasal catarrh. Follow-up for one to thirteen years of the 20 patients with pulmonary tuberculosis revealed that of the 6 who improved 4 are living and well. One other patient is dead. One other has improved but is still under treatment. Of the 14 patients who did not improve with this treatment, 6 are living and 8 are dead.

Relief of Peripheral Vascular Pain.—Siris and Kahn treated 2 men aged 60 and 46, with intractable peripheral vascular pain, by interlaminar rhizotomy. A spinal anesthesia vasomotor test performed on the first patient three months

before the rhizotomy showed definite evidence of organic vascular occlusive disease involving both lower extremities, more pronounced on the right side. A right lumbar sympathectomy with excision of the second and third lumbar ganglions relieved the radiating pain in the limb, but severe pain still persisted in the right first toe about the site of a gangrenous process in the ungual region. Because of the persistence of pain a posterior rhizotomy of the right fourth and fifth lumbar roots was carried out. Following intervention the pain was appreciably less. Two months after the operation healing of the great toe was noted. Apart from a slight weakness of dorsiflexion of the right foot no demonstrable limitation of motor power was observed. The second patient presented decided edema of the right foot, ankle and lower leg. A dry gangrenous plaque was present on the plantar surface of the first right toe and an infected gangrenous fissure at the base of the right fifth toe. Paravertebral sympathetic block at the first to fourth lumbar vertebrae was carried out on three occasions with immediate but only temporary relief. To effect permanent relief of the patient's pain the posterior roots of the fifth lumbar and the first sacral nerves on the right side were sectioned under spinal anesthesia. This resulted in considerable relief of the pain in the patient's toes, associated with hypesthesia corresponding to the dermatomes of the sectioned roots. There was no evidence of foot drop or other motor weakness. Three months after the operation the patient was able to resume his work as a car washer in a garage without pain or discomfort in the foot. It was felt that the procedure possibly spared each of these patients an amputation. It appears that relief of angiospasm in these cases, apart from the associated relief of pain, is attributable to abolition of the vasospastic reflex evoked by the pain factor.

Public Health Reports, Washington, D. C.

64:1-40 (Jan. 7) 1949

- *Tuberculosis Control Program of Nine California Mental Institutions: Results of Initial Chest X-Ray Survey. W. R. Oechsli.—p. 4.
- *Tuberculin, Coccidioidin, and Histoplasmin Sensitivity in Relation to Pulmonary Calcifications: Survey Among 6,000 Students at University of Chicago. W. G. Beadenkopf, C. G. Loosli, H. Lack and others.—p. 17.

Tuberculosis in Mental Institutions.—According to Oechsli, roentgen survey of general hospital patients is recognized as a productive field for tuberculosis case finding; mental institutions provide an even more productive field of investigation. A tuberculosis death rate of over 600 per 100,000 resident population in seven California hospitals for the mentally ill, and a death rate of nearly 400 per 100,000 resident population in two institutions for the mentally defective indicated the same need in California as in other states for an effective program of case finding and tuberculosis control. A prevalence of 8.25 per cent of previously unsuspected reinfection type pulmonary tuberculosis was discovered among 25,914 patients in seven mental hospitals. Prevalence of tuberculosis was higher among patients with dementia precox than among those with other mental conditions. This is probably because patients with dementia precox stay in the hospital longer and therefore have greater opportunity for exposure. A program of segregation was put into effect. All patients with active pulmonary disease were segregated; also, some of the patients with questionably active or potentially communicable disease. Patients with inactive disease were left on nontuberculous wards but checked periodically by roentgen ray. Among employees of mental hospitals there was a prevalence of 2.7 per cent pulmonary tuberculosis. The prevalence of reinfection type pulmonary tuberculosis in two institutions for the mentally defective was 1.2 per cent, much lower than among mentally ill patients. This difference is attributed to the younger age at which the mentally defective are admitted. Among employees in institutions for mentally defective persons the prevalence was 1.4 per cent.

Tuberculin, Coccidioidin and Histoplasmin Sensitivity in Relation to Pulmonary Calcifications.—Beadenkopf and his associates say that in view of the evidence that histoplasmosis and coccidioidomycosis may be etiologically associated with pulmonary calcification these antigens were included among the skin tests given as part of the tuberculosis control program

at the University of Chicago. Only 30 per cent of the students enrolled come from Chicago and vicinity; the greater number are drawn from practically all parts of the United States, and several hundred are from foreign countries. The present report is based on the study of 6,000 students registered at the University from January 1 to October 1947. This study on a population of diverse origin confirms the results of other recent surveys. It was found that (1) the prevalence of tuberculin sensitivity progressively increased from 10 per cent among the youngest age group to 57 per cent among those 50 years of age; (2) the rate of histoplasmin sensitivity began at 10 per cent among the youngest group and reached 38 per cent in the oldest group; (3) pulmonary calcifications were associated with histoplasmin sensitivity twice as frequently as they were with tuberculin sensitivity, and (4) the prevalence of both histoplasmin sensitivity and pulmonary calcifications was highest in the Lower Mississippi Basin of the United States.

Ancient Experience with Intoxicating Drinks: Non-Classical Peoples. A. P. McKinlay.—p. 388.

Motivational Pattern of Drinking.—Riley and his associates say that as a result of a nationwide survey of public attitudes concerning the drinking of alcoholic beverages data were acquired which support three hypotheses related to motivation for drinking. In the first place, they suggest the feasibility of applying standard analytic procedures to this aspect of the problem of consumption of alcoholic beverages. Secondly, the data lend powerful support to the hypothesis that drinking is as directly motivated by the influence of social pressures as it is by acquired inner drives. Thirdly, the relative weight of external social pressures versus inner acquired drives varies widely between different classes of drinkers. Direct social pressure is much more influential in motivating the drinking of women compared with men; the young compared with the old, and the occasional or infrequent compared with regular drinkers. On the other hand, regular drinkers tend to state that their reasons for drinking lie more within themselves than in the pressures from the group. Discussing the question of prevention, the authors cite among others an admonition emphasized by the National Committee for Education on Alcoholism; "Never insist on any one taking a drink." The effect of instituting such a small change in fashion, for example, as the serving of both alcoholic and nonalcoholic beverages at gatherings, and in such a manner that either choice seems appropriate might be far reaching. Certainly for the alcoholic addict who has regained his sobriety it would have significance, for he knows that he must not take one drink. In addition, there are those adults who do not like to drink, or have been ordered not to drink, but "choke it down just to be sociable." Finally, and probably of greatest significance, are the younger persons who have not yet accepted the view that drinking always goes with sociability.

Primary Carcinoma of the Gallbladder.—The 19 cases of carcinoma of the gallbladder reported by Garipey and Gardner were observed at a Detroit hospital in eight years, when a total of 1,777 operations were done. Thus the surgical inci-

dence of carcinoma of the gallbladder was slightly over 1 per cent. In the gastrointestinal tract only the stomach, colon, rectum and esophagus are more often the site of cancer than is the gallbladder. The etiology of carcinoma of the gallbladder is not clear, but the authors feel that the relationship of cholelithiasis to carcinoma deserves special attention. Sixteen of their 19 patients had calculi in the gallbladder. In other reports the incidence of the concurrence of cancer and stones of the gallbladder varies between 36 and 100 per cent. Cholecystitis is invariably present. Eleven of the 19 patients were in the sixth decade of life, when this type of carcinoma is regarded as most frequent. Fourteen of the patients were women, and other literature reports likewise stress the much higher incidence in women than in men. The correct diagnosis was not made preoperatively in any of the 19 cases. Icterus was present in 13 of the 19 cases. Loss of weight is a significant factor. A primary tumor of the head of the pancreas had been suspected in some of the cases; however, in the majority of instances, a diagnosis of chronic cholecystitis and cholelithiasis was given. The authors treated 13 of their 19 patients by cholecystectomy with or without the removal of the adjacent hepatic beds; 5 were treated by cholecystostomy for drainage, and one advanced neoplastic process was treated by a gastroenterostomy. Five of the 16 patients that could be traced were living from eighteen months to seven years after the operation; 1 patient died three years after the operation, and the remaining ones all died within fifteen months. The 5 in whom hepatic metastases were observed at the time of operation all died in less than eight months. In view of the frequent concurrence of cancer with cholelithiasis, the authors regard prophylactic removal of gallbladders harboring stones as imperative.

Hepatic Function Tests.—Klatskin shows that few of the tests employed actually measure normal physiologic functions of the liver. Thus, while changes in the level of serum albumin and bilirubin or in the excretion of galactose may indicate disturbances in normal functions, the excretion of a foreign dye, such as sulfobromophthalein sodium, cannot be regarded as a measure of any of the normal functions of the liver, even though it may reflect abnormalities in them indirectly. Some of the tests measure changes which, while they may disclose the presence of pathologic processes in the liver, do not necessarily imply any abnormality in its functions. Features of the liver which make it peculiarly difficult to study include the multiplicity of its functions, not all of which are equally or simultaneously affected in disease; its tremendous reserve and regenerative power, which permit extensive damage or removal of tissue before any of its functions are disturbed, and the intimate anatomic relationships of its glandular, excretory and vascular components, which make for complex functional disturbances, even when the initial injury is confined to one component. It is not difficult to understand why early attempts to find a single comprehensive test of hepatic function were bound to fail. The recent trend has been toward the use of a battery of tests. Unfortunately, as the number and sensitivity of the tests increase, they become increasingly difficult to interpret. The author discusses the tests that have been in use at Yale University School of Medicine. He reaches the conclusion that hepatic function tests have their greatest value in the diagnosis of subclinical disease of the liver and in following the course of overt disease of the liver. They are of far less value than are the history, physical examination and other clinical data in the differential diagnosis of outspoken disease and are, at best, confirmatory.

Antihistamine Drug in Acute Nephritis.—Craig and his co-workers point out that the tendency for acute nephritis to occur at an interval of a week or two after an acute bacterial infection suggests that nephritis may be in the nature of an allergic response to bacterial toxins. The relationship which seems to exist between acute nephritis and some cases of anaphylactoid purpura lends further support to this theory. The authors tested the effect of antihistamine drugs in patients with acute nephritis. They give an account of 8 cases in which they used the antihistamine drug pyranisamine maleate (anthisan,[®] neoantergan maleate[®]). They compare the course of these cases with that of 9 consecutive cases of acute nephritis treated in the same hospital during the period immediately preceding the institution of this treatment. The duration of activity of the disease, as assessed by abnormal findings in the urine, is notably shorter in the cases in which treatment is with pyranisamine maleate than in those of the control group. The antihistamine drug was given in doses of 0.1 Gm. three times a day. The authors have formed no definite opinions on optimum dosage or duration of treatment. In some cases the administration of the drug was stopped when all abnormal signs disappeared; in others it was continued for a further week or two. They feel that since acute nephritis is a disease which may run a variable course, no final evaluation of the described treatment is possible on the basis of the small number of cases.

Studies in Lung Abscess. R. C. Brock.—p. 75.

Blalock-Taussig Operation for Morbus Caeruleus.—Campbell describes the steps that led to the development of the Blalock-Taussig operation for cyanotic congenital heart disease and says that the fundamental requisite for success is that the cyanosis and disability should be mainly due to an inadequate blood flow to the lungs. The first 18 patients chosen at Guy's Hospital and operated on by Blalock or by Brock are described. The main features on which these patients were selected were persistent cyanosis from infancy with polycythemia and clubbing of the fingers and severe disability on walking. On radioscopy the heart showed little or no general enlargement, though most patients had some enlargement of the right ventricle. Most of them had a systolic murmur in the pulmonary area, often with a slight thrill. All were of normal mental development, but most were under weight. Squatting was noted in four fifths and panting after exertion was nearly as characteristic. The operation was usually an end to side subclavian-pulmonary anastomosis on the side opposite to the aortic arch: this was right-sided in one quarter. The immediate upset caused by the operation is less than might be expected. Three of the 18 died; 1 could not have an anastomosis done, and 1 did not benefit much. The remaining 13 were enormously improved almost at once, and the improvement has been maintained or increased for the three to six months that have elapsed since the operation. The polycythemia disappeared quickly and the

clubbing of the fingers more slowly. Fallot's tetralogy seems the probable diagnosis in about three quarters of the cases of congenital heart disease in which cyanosis dates from birth or early in life. The high mortality without operation justifies the risk involved in the Blalock-Taussig operation. Auricular septal defect (combined with some other defect causing cyanosis from birth or soon after) seems to be the commonest abnormality contraindicating operation. The condition of the pulmonary arterial branches in radioscopy is the most essential part of the examination. In a doubtful case cardiac catheterization and angiocardiology should be decisive.

*Experiments on Standardization and Keeping Properties of Tetanus Antitoxin in the Tropics. R. K. Goyal.—p. 259.

Standardization and Keeping Properties of Tetanus Antitoxin.—Goyal presents studies which indicate that it is

not possible for a drug control laboratory to determine the exact unitage of any sample of tetanus antitoxin, unless a standard toxin or a standard strain of the *Clostridium tetani* is used. It might not be convenient to compel all laboratories and manufacturing concerns throughout the world to use a particular toxigenic strain of *Cl. tetani* for production of toxin; it should, however, be possible to lay down the use of a selected strain by all the manufacturers in India to enable the standardization laboratories to arrive at a reliable and satisfactory figure with regard to the unitage of tetanus antitoxins. The possibility of variation due to the use of a heterologous test toxin for titrating imported tetanus antitoxin cannot be ruled out in the absence of a concerted international agreement about the universal employment of a standard strain for toxin manufacture. Discussing the keeping properties of tetanus antitoxin serums, the author says that manufacturers add an extra unitage at the time of issue of antitoxins to allow for deterioration during storage. It appears that the extra unitage allowed for is not calculated on any scientific basis. The author titrated a number of samples of tetanus antitoxic serums with the same toxin at various intervals. He found that the rate of deterioration is apparently affected by the physical properties of the serum, which are dependent to some extent on the method of concentration. The rate of deterioration of the serum in the case of the enzyme-disaggregated product (RD-244-D) was much less than in serums concentrated by ammonium sulfate. In temperate countries, extra unitage is allowed on the basis of 10 per cent per year deterioration of the serum. On titration of eight samples of antitoxic serums obtained from England and Australia, an extra unitage of 25 per cent to 80 per cent was found. Since in India antitoxin has been noted to deteriorate at the rate of 24 per cent per year, the author believes that Indian manufacturers should add at least 30 per cent extra unitage for each year of storage.

Iron-Sucrose Preparation for Intravenous Use.—Slack and Wilkinson describe a method of preparing an iron-sucrose preparation which contains 2 per cent of elemental iron and which they have given intravenously in repeated doses to over

120 persons. They report on the hematologic responses of the first 60 patients with iron deficiency anemia. About a third of these have been treated with the aforementioned preparation, and the remainder have had another form of iron-sucrose preparation. There has been no detectable difference in tolerance or response in many batches of either of these two preparations. The authors gained the impression that these iron-sucrose preparations are relatively safe and effective vehicles for giving iron parenterally. Reactions, if any, were mild, and only four small local venous thromboses have occurred in over eight hundred injections. The authors conclude that these preparations will be valuable in the treatment of iron deficiency anemia that has proved refractory to iron given by mouth, or of patients who do not tolerate iron by mouth in adequate doses.

*Metastasis of Cancer of Breast to Ovary. A. Ameline and Y. Chatain.—p. 536.

Ovarian Metastasis.—Ameline and Chatain report 1 case of bilateral ovarian metastasis of cancer of the breast in a woman aged 58. Radical amputation of the breast including dissection of the axilla was performed in March 1945. The patient was followed up to May 1948, when she complained of hypogastric heaviness. In the pelvis two hard, mobile masses were observed on palpation. Laparotomy revealed two enormous ovarian tumors and infiltration of the utero-ovarian pedicles. Low subtotal hysterectomy was performed. Microscopic examination of the specimen revealed ovarian tumors of polymorphous, extremely atypical malignant type with spread of the neoplasm to the uterus associated with uterine endometriosis. In August 1948 the patient's condition was still satisfactory but prognosis highly unfavorable. Total hysterectomy with removal of the adnexa rather than subtotal hysterectomy is the treatment of choice for ovarian metastasis spreading to the uterus. Castration should be performed in all cases of inoperable cancer of the breast, and surgical intervention is to be preferred to radiotherapy. In young women with regular menstruation and operable neoplasm of the breast, oophorectomy should be performed provided that the clinical aspect is suggestive of considerable malignancy. Supportive "hormone" treatment is to be considered as still in the experimental stage.

*Juxtacardiac Ulcer and Ulcer of Upper Third of Stomach: Surgical Treatment by Kelling-Madlener's Operation. A. Reccius.—p. 2313.

*Clinical Aspects of Cardiovascular Brucellosis. I. Maldonado-Allende.—p. 2323.

Juxtacardiac Ulcer.—Reccius shares Kelling's opinion that a successful surgical treatment of juxtacardiac ulcer, after failure of medical treatment, does not necessarily consist of the removal of the ulcer but of creating favorable local conditions for the healing of the ulcer. The operation which possesses the necessary requirements is the so-called palliative resection of the antropylopic region of the stomach. The author resorted to antropylorectomy by Kelling-Madlener's technic in 24 patients. The operation was performed without touching or cauterizing the ulcer. There were neither postoperative complications nor death. The gastric disorders disappeared rapidly and perma-

nently. Fourteen of the patients were followed up for three to fourteen years. Ten had had the operation in the last two years. The clinical symptoms disappeared in all patients. Repeated roentgen examinations showed disappearance of the niche. The author concludes that palliative resection by Kelling-Madlener's technic is indicated in juxtacardiac ulcer, in ulcer of the upper third of the lesser curvature and in ulcer of the cardiac portion of the stomach. The results of the operation, both immediate and permanent, in all the patients observed by the author were excellent. This operation is to be preferred to a gastroenterostomy.

Clinical Aspects of Cardiovascular Brucellosis.—Maldonado-Allende observed 428 cases of brucellosis in the course of the last five years in patients cared for at the Hospital Argentino de Clínicas and in the Centro Cardiológico Nacional. Brucella lesions of the cardiovascular system were encountered in 55 cases in the group. The cardiovascular disorders were predominantly brucellar in 47 cases. There was chronic brucellosis in 36 cases, acute brucellosis in 6 cases and subacute brucellosis in 6 cases. The following cardiovascular disorders were encountered: branch block in 6 cases, arborization block in 1, auriculoventricular block in 1, subacute coronary insufficiency in 3 and myocardial infarction in 2. Extrasystolic arrhythmia was frequent, being the predominant complaint of 4 patients. There was fibrillation in 2 cases. Aortitis was present in 2. Among the group of patients under 40 years of age arterial hypotension was encountered in 12 and hypertension in 22. Tachycardia was present in all cases of brucellosis, acute or subacute. In chronic forms of the disease with cardiovascular complication tachycardia was so constantly encountered as to be considered of diagnostic value. Auricular paroxysmal tachycardia was present in 1 case. There was constant and pronounced neurocirculatory asthenia in 4 cases. Endocarditis was not present in any case. The author emphasizes the need of directing attention to the brucellar causation of pericarditis in cases of the disease of obscure origin. The pericardium may be involved in a similar manner as the pleural serosa. The involvement of the myocardium, rather than of the endocardium, is the most frequent cardiovascular complication of chronic and acute brucellosis. Reversibility of the cardiovascular symptoms was rare and only temporary. Cardiovascular complications of brucellosis constitute a clinical cardiac form of brucellosis, which calls for diagnosis in cases of cardiovascular disease of unknown etiology.

Value of Respiratory Type as a Secondary Sexual Character in Adults. E. May.—p. 897.

*Place to be Given to Adrenalectomy in Treatment of Arteritis. L. Leger, A. Mathivat and S. Tchekoff.—p. 898.

Volatile Antibiotics; Beta-Antibiotics. W. N. Markoff.—p. 901.

Adrenalectomy for Arteritis.—Leger and his co-workers performed adrenalectomy on 25 patients between the ages of 31 and 64 with arteritis. There was no operative death. No signs of cortical insufficiency were observed in the patients operated on. On the contrary, functional improvement was superior to that obtained by drugs or other surgical interventions. Three-fourth of the 25 patients were followed up for two years. Good results were obtained in 8 patients, medium results in 2 and 3 were failures. Not one of the 13 patients had to undergo post-operative amputation, and even in those with medium results and in the failures there was no progression of the pathologic process and the lesions were stabilized. Although adrenalectomy may not be the method of choice in all cases of arteritis, the results obtained with this method in young and middle-aged patients warrant its employment, particularly in those in whom the gangrenous lesions are little advanced and the arterial involvement still shows a tendency to spasms. Adrenalectomy should not be practiced in cases in which the spasmodic element has given place to organized thrombosis. In patients of advanced aged intervention on the sympathetic nerve should be done first, but in case of failure adrenalectomy may be justified, as in 2 of the author's patients aged 60 and 64 respectively.

Book Notices

A Course in Practical Therapeutics. By Martin Emil Rehfuss, M.D., F.A.C.P., Professor of Clinical Medicine and Sutherland M. Prevost, Lecturer in Therapeutics, The Jefferson Medical College of Philadelphia; F. Kenneth Albrecht, M.D., and Allison Howe Price, A.B., M.D., Asst. Professor of Medicine, The Jefferson Medical College of Philadelphia. Cloth. Price, \$15. Pp. 824, with 70 plates. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1948.

This book is an attempt to collate the essential information that has been gathered over a considerable period in teaching departments at the Jefferson Medical College of Philadelphia. It is intended, as the title suggests, to offer discussions on "the entire field of therapeutics in one volume." The contents include chapters on general therapeutic principles, symptomatic therapy, treatment of specific disorders and special treatment. The editors frankly admit "there is undoubtedly much to criticize," but probably the average person who turns to this book will overlook some of the causes for criticism because of some excellent features, such as the inclusion of plates that permit visual understanding of a variety of perplexing problems, such as headache, chronic nephritis, contact dermatitis, acute pancreatitis and brucellosis. The book could be criticized on the grounds that it is not sufficiently critical of some of the measures that are used—for example, vitamin E—but, on the other hand, it does provide details of technics, such as the administration of heparin, which offer useful information often unobtainable in reference books. If this book goes into a second edition it is likely that some of the causes for criticism will be removed, but even in its present form it undoubtedly will be well received by many who like their information presented in succinct and orderly fashion.

A Textbook of Histology. By Alexander A. Maximow and William Bloom, Professor of Anatomy, University of Chicago. Fifth edition. Cloth. Price, \$8.50. Pp. 700, with 562 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London W.C. 2, 1948.

Previous editions of this textbook of histology have been reviewed in *THE JOURNAL*, and all reviews have been commendatory. The present edition is likewise excellent. The author seems to differ from some other investigators in certain interpretations of histologic and pathologic observations; however, he gives also the point of view of those with whom he may differ. For example, he believes that "the macrophage system" is a more appropriate term than the "reticuloendothelial system," apparently because Metchnikoff was the first to recognize this system of cells, which he called macrophages, as belonging to a single physiologic system and to see clearly the function of these cells in inflammation and immunity. Generally, however, the term reticuloendothelial system as defined by Aschoff has come into more widespread use. The numerous illustrations in this book are outstandingly clear, well selected and informative.

One of the most notable changes in this edition is in the makeup of the book whereby the width of the line of type is only half the width of the lines in the previous edition; that is, each page has two columns instead of being solid as before, and this adds to the ease and speed of reading. A minor oversight in the makeup is the beginning of a paragraph in the last line on the page, which is done in numerous places; for example, pages 87, 111 and 627. This minor point, it seems, could have been readily corrected by a little more supervision of the inters. Another minor oversight appears on page 47, where it is stated that a certain discussion will be found on "page 000." There is no such page in the book.

Study on Vitamin 'P.' Part I: Capillary Permeability and Fragility. Boris Th. Sokoloff, M.D., Ph.D., Associate Director of Research, and James B. Redd, Ph.D., Director, Citrus School, Florida Southern College, Lakeland, Florida. Florida Southern College, Monograph 1. Paper. .39, with 3 illustrations. Florida Southern College, Lakeland, Florida, 19.

This pamphlet presents a discussion of capillary permeability and fragility, and presumably is intended to advance arguments concerning the relation of the so-called vitamin "P" to permeability and fragility of the capillaries.

Education Through Physical Activities: Physical Education and Recreation for Elementary Grades. By Patricia Ruth O'Keefe, Ph.D., Director of Health and Physical Education, and Helen Fahey, A.M., Supervisor of Health and Physical Education, Kansas City, Missouri, Public Schools. Cloth. Price, \$4. Pp. 309, with illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1949.

This book presents a program of physical recreation activities which can be included in elementary school physical education. Purposes of a good program, it is pointed out, must extend beyond exercise to include opportunities for social and recreational learnings as well as for improved mental and emotional health. The authors have attempted to show how the program can be developed on a worth while basis in the many varying situations found in American elementary schools. Attention has been given to the fact that available facilities and space will make a difference in the kind of program that can be conducted.

The material is divided into four sections. The first section is devoted to principles of child growth and development as they apply to physical education and the factors involved in selection of activities and program planning and evaluation. The second part details suggested activities for the outdoor program, including methods of organizing and planning informal play periods and classwork in physical education. Section three is devoted to indoor activities, with emphasis on adapting materials of instruction to the existing situation. Suggestions are outlined for using the classrooms, halls and other available spaces for physical education as a temporary expedient when no gymnasium is available. Both indoor and outdoor activities are grouped in two categories on a grade level basis; namely, those for primary children in grades 1, 2 and 3 and those for intermediate children in grades 4, 5 and 6.

It is hoped that the publication of another guide of this kind will be a stimulus to the development of more effective physical education at the elementary school level. Despite the recognition of both the medical and educational professions that the elementary schools offer the most fertile field for developmental activities, the best programs and best prepared teachers are generally found in the secondary schools.

The book is noteworthy in that an effort has been made to present the materials in a way that will be intelligible to the classroom teacher and lay leader of youth groups, as well as the professionally trained physical educator. While the volume will prove of greatest value as a textbook in teacher education and a guide for teachers and school administrators in service, it will also be of interest to school medical advisers and physicians serving on boards of education or on school health committees.

An Introduction to Dermatology. Formerly by Norman Walker, M.D., LL.D., and G. H. Percival, M.D., Ph.D., F.R.C.P.E. Eleventh edition by G. H. Percival, Grant Professor of Dermatology, the University of Edinburgh, Edinburgh. Cloth. Price, \$9. Pp. 349, with 233 illustrations. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1947.

This book offers much more than one could expect from the title. Only the author's clear and concise style has made possible the inclusion of such voluminous material, rarely found in books of this size. The anatomic, biologic, embryologic, physiologic, allergic, bacteriologic, pathologic and endocrinologic basis of the various cutaneous manifestations are dextrously woven into a harmonious clinical pattern easy to comprehend. The common dermatoses are fully described; the rarer ones less completely. The illustrations, many of which are colored, are excellent. The book contains a wealth of practical information as to diagnosis and therapy, seldom encountered in one large dermatologic book. The external treatment of cutaneous disorders is thoroughly discussed and illustrated. Emphasis is also placed on the internal treatment of various dermatoses. Especially stimulating and elucidative is the author's classification and delineation of the complex disease eczema, according to the nature of the precipitating factors, into six types, and the subdivision again of one of the groups, infective eczema, into four main types. The book was written primarily for students and beginners in dermatology. General practitioners will find it a most welcome addition to their libraries.

120 persons. They report on the hematologic responses of the first 60 patients with iron deficiency anemia. About a third of these have been treated with the aforementioned preparation, and the remainder have had another form of iron-sucrose preparation. There has been no detectable difference in tolerance or response in many batches of either of these two preparations. The authors gained the impression that these iron-sucrose preparations are relatively safe and effective vehicles for giving iron parenterally. Reactions, if any, were mild, and only four small local venous thromboses have occurred in over eight hundred injections. The authors conclude that these preparations will be valuable in the treatment of iron deficiency anemia that has proved refractory to iron given by mouth, or of patients who do not tolerate iron by mouth in adequate doses.

*Clinical Aspects of Cardiovascular Brucellosis. I. Maldonado-Allende.—p. 2323.

Juxtacardiac Ulcer.—Reccius shares Kelling's opinion that a successful surgical treatment of juxtacardiac ulcer, after failure of medical treatment, does not necessarily consist of removal of the ulcer but of creating favorable conditions for the healing of the ulcer. The necessary requirements is the presence of the antropylopic region of the stomach to antropylorectomy by Kelling-Madlener's operation was performed with the ulcer. There was a favorable post-operative result. The gastric dis-

section was performed. Fourteen of the patients were followed up for three to fourteen years. Ten had had the operation in the last two years. The clinical symptoms disappeared in all patients. Repeated roentgen examinations showed disappearance of the niche. The author concludes that palliative resection by Kelling-Madlener's technic is indicated in juxtacardiac ulcer, in ulcer of the upper third of the lesser curvature and in ulcer of the cardiac portion of the stomach. The results of the operation, both immediate and permanent, in all the patients observed by the author were excellent. This operation is to be preferred to a gastro-enterostomy.

Clinical Aspects of Cardiovascular Brucellosis.—Maldonado-Allende observed 428 cases of brucellosis in the course of the last five years in patients cared for at the Hospital Argentino de Clínicas and in the Centro Cardiológico Nacional. Brucella lesions of the cardiovascular system were encountered in 55 cases in the group. The cardiovascular disorders were predominantly brucellar in 47 cases. There was chronic brucellosis in 36 cases, acute brucellosis in 6 cases and subacute brucellosis in 6 cases. The following cardiovascular disorders were encountered: branch block in 6 cases, arborization block in 1, auriculoventricular block in 1, subacute coronary insufficiency in 3 and myocardial infarction in 2. Extrasystolic arrhythmia was frequent, being the predominant complaint of 4 patients. There was fibrillation in 2 cases. Aortitis was present in 2. Among the group of patients under 40 years of age arterial hypotension was encountered in 12 and hypertension in 22. Tachycardia was present in all cases of brucellosis, acute or subacute. In chronic forms of the disease with cardiovascular complication tachycardia was so constantly encountered as to be considered of diagnostic value. Auricular paroxysmal tachycardia was present in 1 case. There was constant and pronounced neurocirculatory asthenia in 4 cases. Endocarditis was not present in any case. The author emphasizes the need of directing attention to the brucellar causation of pericarditis in cases of the disease of obscure origin. The pericardium may be involved in a similar manner as the pleural serosa. The involvement of the myocardium, rather than of the endocardium, is the most frequent cardiovascular complication of chronic and acute brucellosis. Reversibility of the cardiovascular symptoms was rare and only temporary. Cardiovascular complications of brucellosis constitute a clinical cardiac form of brucellosis, which calls for diagnosis in cases of cardiovascular disease of unknown etiology.

Presse Médicale, Paris

56:897-908 (Dec. 25) 1948. Partial Index

Value of Respiratory Type as a Secondary Sexual Character in Adults. E. May.—p. 897.

*Place to be Given to Adrenalectomy in Treatment of Arteritis. L. Leger, A. Mathivat and S. Tchekoff.—p. 898.

Volatile Antibiotics; Beta-Antibiotics. W. N. Markoff.—p. 901.

Adrenalectomy for Arteritis.—Leger and his co-workers performed adrenalectomy on 25 patients between the ages of 31 and 64 with arteritis. There was no operative death. No signs of cortical insufficiency were observed in the patients operated on. On the contrary, functional improvement was superior to that obtained by drugs or other surgical interventions. Thirteen of the 25 patients were followed up for two years. Good results were obtained in 8 patients, medium results in 2 and 3 were failures. Not one of the 13 patients had to undergo post-operative amputation, and even in those with medium results and in the failures there was no progression of the pathologic process and the lesions were stabilized. Although adrenalectomy may not be the method of choice in all cases of arteritis, the results obtained with this method in young and middle-aged patients warrant its employment, particularly in those in whom the gangrenous lesions are little advanced and the arterial involvement still shows a tendency to spasms. Adrenalectomy should not be practiced in cases in which the spasmodic element has given place to organized thrombosis. In patients of advanced arteritis, intervention on the sympathetic nerve should be done first, and in case of failure adrenalectomy may be justified, as in 2 of the author's patients aged 60 and 64 respectively.

Book Notices

A Course in Practical Therapeutics. By Martin Emil Rehfuss, M.D., F.A.C.P., Professor of Clinical Medicine and Sutherland M. Prevost Lecturer in Therapeutics, The Jefferson Medical College of Philadelphia; F. Kenneth Albrecht, M.D., and Allison Howe Price, A.B., M.D., Asst. Professor of Medicine, The Jefferson Medical College of Philadelphia. Cloth. Price, \$15. Pp. 824, with 70 plates. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1948.

This book is an attempt to collate the essential information that has been gathered over a considerable period in teaching departments at the Jefferson Medical College of Philadelphia. It is intended, as the title suggests, to offer discussions on "the entire field of therapeutics in one volume." The contents include chapters on general therapeutic principles, symptomatic therapy, treatment of specific disorders and special treatment. The editors frankly admit "there is undoubtedly much to criticize," but probably the average person who turns to this book will overlook some of the causes for criticism because of some excellent features, such as the inclusion of plates that permit visual understanding of a variety of perplexing problems, such as headache, chronic nephritis, contact dermatitis, acute pancreatitis and brucellosis. The book could be criticized on the grounds that it is not sufficiently critical of some of the measures that are used—for example, vitamin E—but, on the other hand, it does provide details of technics, such as the administration of heparin, which offer useful information often unobtainable in reference books. If this book goes into a second edition it is likely that some of the causes for criticism will be removed, but even in its present form it undoubtedly will be well received by many who like their information presented in succinct and orderly fashion.

A Textbook of Histology. By Alexander A. Maximow and William Bloom, Professor of Anatomy, University of Chicago. Fifth edition. Cloth. Price, \$8.50. Pp. 700, with 562 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London W.C. 2, 1948.

Previous editions of this textbook of histology have been reviewed in *THE JOURNAL*, and all reviews have been commendatory. The present edition is likewise excellent. The author seems to differ from some other investigators in certain interpretations of histologic and pathologic observations; however, he gives also the point of view of those with whom he may differ. For example, he believes that "the macrophage system" is a more appropriate term than the "reticuloendothelial system," apparently because Metchnikoff was the first to recognize this system of cells, which he called macrophages, as belonging to a single physiologic system and to see clearly the function of these cells in inflammation and immunity. Generally, however, the term reticuloendothelial system as defined by Aschoff has come into more widespread use. The numerous illustrations in this book are outstandingly clear, well selected and informative.

One of the most notable changes in this edition is in the makeup of the book whereby the width of the line of type is only half the width of the lines in the previous edition; that is, each page has two columns instead of being solid as before, and this adds to the ease and speed of reading. A minor oversight in the makeup is the beginning of a paragraph in the last line on the page, which is done in numerous places; for example, pages 87, 111 and 627. This minor point, it seems, could have been readily corrected by a little more supervision of the printers. Another minor oversight appears on page 47, where it is stated that a certain discussion will be found on "page 000." There is no such page in the book.

Study on Vitamin 'P.' Part I: Capillary Permeability and Fragility. By Boris Th. Sokoloff, M.D., Ph.D., Associate Director of Research, and James B. Redd, Ph.D., Director, Citrus School, Florida Southern College, Lakeland, Florida. Florida Southern College, Monograph 1. Paper. Pp. 39, with 3 illustrations. Florida Southern College, Lakeland, Florida, 1949.

This pamphlet presents a discussion of capillary permeability and fragility, and presumably is intended to advance arguments concerning the relation of the so-called vitamin "P" to permeability and fragility of the capillaries.

Education Through Physical Activities: Physical Education and Recreation for Elementary Grades. By Patricia Ruth O'Keefe, Ph.D., Director of Health and Physical Education, and Helen Fahey, A.M., Supervisor of Health and Physical Education, Kansas City, Missouri, Public Schools. Cloth. Price, \$4. Pp. 309, with illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1949.

This book presents a program of physical recreation activities which can be included in elementary school physical education. Purposes of a good program, it is pointed out, must extend beyond exercise to include opportunities for social and recreational learnings as well as for improved mental and emotional health. The authors have attempted to show how the program can be developed on a worth while basis in the many varying situations found in American elementary schools. Attention has been given to the fact that available facilities and space will make a difference in the kind of program that can be conducted.

The material is divided into four sections. The first section is devoted to principles of child growth and development as they apply to physical education and the factors involved in selection of activities and program planning and evaluation. The second part details suggested activities for the outdoor program, including methods of organizing and planning informal play periods and classwork in physical education. Section three is devoted to indoor activities, with emphasis on adapting materials of instruction to the existing situation. Suggestions are outlined for using the classrooms, halls and other available spaces for physical education as a temporary expedient when no gymnasium is available. Both indoor and outdoor activities are grouped in two categories on a grade level basis; namely, those for primary children in grades 1, 2 and 3 and those for intermediate children in grades 4, 5 and 6.

It is hoped that the publication of another guide of this kind will be a stimulus to the development of more effective physical education at the elementary school level. Despite the recognition of both the medical and educational professions that the elementary schools offer the most fertile field for developmental activities, the best programs and best prepared teachers are generally found in the secondary schools.

The book is noteworthy in that an effort has been made to present the materials in a way that will be intelligible to the classroom teacher and lay leader of youth groups, as well as the professionally trained physical educator. While the volume will prove of greatest value as a textbook in teacher education and a guide for teachers and school administrators in service, it will also be of interest to school medical advisers and physicians serving on boards of education or on school health committees.

An Introduction to Dermatology. Formerly by Norman Walker, Kt., M.D., LL.D., and G. H. Percival, M.D., Ph.D., F.R.C.P.E. Eleventh edition by G. H. Percival, Grant Professor of Dermatology, the University of Edinburgh, Edinburgh. Cloth. Price, \$9. Pp. 349, with 233 illustrations. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1947.

This book offers much more than one could expect from the title. Only the author's clear and concise style has made possible the inclusion of such voluminous material, rarely found in books of this size. The anatomic, biologic, embryologic, physiologic, allergic, bacteriologic, pathologic and endocrinologic basis of the various cutaneous manifestations are dextrously woven into a harmonious clinical pattern easy to comprehend. The common dermatoses are fully described; the rarer ones less completely. The illustrations, many of which are colored, are excellent. The book contains a wealth of practical information as to diagnosis and therapy, seldom encountered in one large dermatologic book. The external treatment of cutaneous disorders is thoroughly discussed and illustrated. Emphasis is also placed on the internal treatment of various dermatoses. Especially stimulating and elucidative is the author's classification and delineation of the complex disease eczema, according to the nature of the precipitating factors, into six types, and the subdivision again of one of the groups, infective eczema, into four main types. The book was written primarily for students and beginners in dermatology. General practitioners will find it a most welcome addition to their libraries.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

DAMAGE TO FETUS BY VIRUS INFECTION OF MOTHER

To the Editor:—A healthy young woman, in her third month of a pregnancy, gives a history of having suffered an attack of varicella in the first month of pregnancy. 1. What is the possibility of damage to the fetus by this virus infection? 2. Should termination of pregnancy be considered? 3. Has work been done on the relation between maternal virus infections during pregnancy and congenital defects of the newborn, comparable to the studies which have been performed in rubella? M.D., Puerto Rico.

ANSWER:—A fetus may be damaged by varicella but this is much less likely than is the case with rubella. J. J. Prendergast (*Arch. Ophthalmol.* 35:39-41 [Jan.] 1946) cited a case of microphthalmus in a fetus following chickenpox in early pregnancy. C. Wesselhoef (*New England J. Med.* 236:978-988, 1947) expressed the belief that other diseases than rubella, such as measles, mumps, chickenpox, herpes zoster and influenza, may cause defects similar to rubella in the fetus although less often. 2. In view of the infrequency of fetal anomalies in cases of varicella, an abortion should not be performed. 3. The number of cases of fetal abnormalities associated with varicella is small and no special study has been made. An interesting editorial appears in *THE JOURNAL* (138:653-654 [Oct. 30] 1948) on "Congenital Defects" in which the subject of fetal monstrosities due to the passage of viruses through the placental barrier is discussed.

CARPOPEDEAL SPASM

To the Editor:—Recently I was called in to see a 63 year old white Italian man with known hypertension of years' duration. He had suffered some sort of attack while at work associated with fainting which had been diagnosed as a "stroke." When I saw him four hours after this episode he was semicomatose, exhibited Cheyne-Stokes respiration and had a bounding, regular pulse associated with a blood pressure of 230 systolic and 130 diastolic. He also exhibited convulsions, during the cyanotic, apneic phase of his respiratory distress, starting as a lateral deviation of his eyes to the right, deviation of the head to the right, carpopedal spasm on the right and then on the left followed by generalized clonic convulsions. The episode lasted approximately three minutes, ceased, and his color returned to normal. The cycle was repeated numerous times until he died four hours later. It is my impression that this patient suffered a massive intracranial hemorrhage. I can find reference to everything in this picture except the carpopedal spasm in standard neurologic texts. What other mechanism can be postulated to explain them? How common are they in adults? Do they occur in any other conditions except tetany? M.D., Pennsylvania.

ANSWER:—Carpopedal spasm is not a common occurrence in generalized clonic convulsions from cerebral hemorrhage. The most likely explanation is that this man was over-ventilating and had a prolonged overventilation at the peak of Cheyne-Stokes respiration. By this overventilation he produced temporary alkalosis in his blood with the appearance of temporary tetany. During apnea he recovered sufficiently from this alkalosis to stop having tetany. This seems like a possible explanation of this unusual manifestation.

The other possibility is that this was simply extensor rigidity at the beginning of the convulsion, and this would not be so unusual.

TREATMENT OF PIGMENTED MOLE

To the Editor:—Please outline the management of a pigmented mole in a 1 year old child. This mole or nevus is located in the back of the neck and is 1.5 cm. by 1.25 cm. It is colored black and has a small central area which is much darker than the periphery. The central area is the size of a small pea. None of it is elevated or hairy. Is solid carbon dioxide contraindicated? Might such treatment produce malignant reaction? Is excision feasible? Might surgical removal cause a malignant reaction subsequently? Herbert Kornblitt, M.D., Belmont, Mass.

ANSWER:—The general opinion of dermatologists and oncologists is that black moles should be removed, particularly if they are growing, changing color, if they become inflamed or, as in this case, if they are located on an area that is likely to be irritated repeatedly. There is reason to believe that it is best to remove such moles before the onset of puberty, although the evidence for this view is not conclusive. Surgical excision is preferred rather than removal by solid carbon dioxide. Authorities do not believe that surgical removal will cause the development of cancer later.

SALIVATION IN PARKINSONISM

To the Editor:—I am suffering with postencephalitic parkinsonism and am plagued with excess salivation and inability to swallow. The saliva pours out of my mouth as if from a faucet, making it impossible for me to keep up a conversation. These symptoms exaggerate my tremor. Please suggest treatment. M.D., Florida.

ANSWER:—The excessive salivation, which is typical of the postencephalitic form of parkinsonism, is usually readily controlled with one of the belladonna-like drugs which are commonly used in the treatment of this disorder. Atropine is often used for this purpose. The dosage has to be adjusted for each case and should be less than that which will produce the toxic or undesirable effects typical of this drug. Many have found vinobel® particularly efficacious in the treatment of this form of parkinsonism. This is an extract of belladonna in tablet form. Small doses, such as 0.4 mg. once a day, should be used at first and then gradually increased until the maximum desirable relief is obtained. It is the usual practice to increase the dose until mild toxic symptoms are produced and then to reduce the dose slightly. Some patients are able to tolerate as much as 0.8 mg. three or four times a day. With the improvement in salivation and in the control of muscular functions which this drug should produce, it is likely that the patient will also have considerable improvement in his ability to swallow.

FISSURED FINGERTIPS

To the Editor:—A female patient, aged 46, suffers mildly from menopausal symptoms. Her chief complaint is development of fissures over the terminal phalanges during the winter months. Some transverse splitting of the nails also occurs. Neurologic or circulatory disturbances are absent, and results of a complete physical examination and laboratory study are within normal limits. Is this condition considered an entity? What treatment has been found effective? John J. Clancy, M.D., Hartford, Conn.

ANSWER:—The condition of cracked fingertips per se does not constitute a dermatologic entity. Fissures on the fingertips occur not infrequently in association with inflammatory diseases, such as psoriasis, eczema-dermatitis or hyperkeratotic tinea; in association with dry skin due sometimes to hypothyroidism, and, more often, as a result of a combination of factors consisting of trauma, strong soaps and washing powders, particularly in cold weather. Hyperkeratotic plaques, which may become fissured, are occasionally observed on the palms or finger tips of women with keratoderma climactericum, the nosologic position of which has not yet been determined. Some dermatologists consider it a variation of psoriasis or neurodermatitis. Relief usually can be obtained by frequent application of a lubricant containing 5 per cent compound Benzoin tincture in cold cream, an oily base or a water-soluble base. In addition, the woman should use only soft water, a soap substitute and protective gloves in her work.

NUCLEUS PULPOSUS

To the Editor:—1. What are the most common causes of ruptured nucleus pulposus? 2. Has bowling ever been known to be the cause of a ruptured disk? Moody Walker, M.D., Huntsville, Ala.

ANSWER:—The most common cause of ruptured nucleus pulposus is trauma, particularly that which accompanies flexion or torsion of the trunk while lifting heavy weights or pulling against unyielding objects. The onset has often been associated with a patient's falling backward, swinging at an object in an athletic event or stooping to pick an object from the floor. Poor posture and weak paravertebral musculature are believed to be inciting causes.

While specific instances do not come to mind, bowling could cause a herniated nucleus pulposus because of the flexion and torsion of the trunk that it requires. It should not, however, be condemned as an exercise, because it also aids in strengthening the muscles of the back.

PAPILLOMA OF VOCAL CORDS

To the Editor:—A patient (35 years old) has papilloma of the vocal cords. He has been operated on several times without complete success. Is the hormonal treatment of value in males? M.D., Baltimore.

ANSWER:—Hormonal treatment for papilloma of the vocal cords is of dubious value. As employed by Broyles (*South. M. J.* 34:239, 1941) in the treatment of laryngeal papilloma in children, therapy consists in the local application of estrogens (1,000 international units) 0.1 cc. to the laryngeal mucosa once each week for approximately six months.

THE TIME OF DECISION

President's Address

ERNEST E. IRONS, M.D.
Chicago

American medicine under free practice and without compulsion has accomplished results for which it need never apologize. These achievements are indissolubly related to a successful process of education and evolution in a democracy. The continuation of this process must not be halted by a revolutionary change promoted on the basis of such false premises and misstatements as appear in Senate bill 1679, the newest proposal of the present administration. On the basic principle of freedom for American medicine and freedom for America we cannot compromise. Our thirty years' war in behalf of this freedom for American medicine has reached the time of decision.

Our own country has thus far best withstood the strains of total war and the shocks of experiments in planned economy. We have been able to mitigate the sufferings of other nations and to assist them in their attempts to stabilize their governments. True, we have social problems and financial difficulties which need adjustment; they result from changes attendant on our economic evolution, and are in process of cure by this same evolution. As yet we are not insolvent; we have a right to resent the imposition on a virile nation of technics devised for those that are decadent.

As a remedy for deficiencies, shall we stifle the initiative and sense of personal responsibility of our citizens by the importation of a socialism that has failed in Europe? Politically controlled medical care supported by a compulsory tax is an early but essential part of the development of a socialized nation, the forerunner of various forms of collectivism. This fight is not that of medicine alone; it is the fight of all America.

ACHIEVEMENTS OF AMERICAN MEDICINE

Discovery, invention and research have made possible the prevention and cure of disease to an extent previously never imagined. One by one diseases such as pneumonia, meningitis, tuberculosis, venereal diseases, diabetes, diphtheria and pernicious anemia, which formerly were responsible for hundreds of thousands of deaths and incalculable days of illness, are being controlled by new remedies or prevented by appropriate medical and sanitary measures. Extension of local and county health units is proceeding under the stimulation and supervision of state and local medical societies, the United States Public Health Service and the American Public Health Association. All these measures are

based on the store of medical and scientific knowledge built up, bit by bit, by medical research. Deaths from lobar pneumonia in metropolitan hospitals, formerly 20 to 45 for every 100 persons who were infected, have been reduced to 7 or less. Last year forty cities in the United States did not have a single death from diphtheria. The expectation of duration of life at birth in 1900 was 49 years; in 1949 it is 68 years. One thousand babies born in 1950 are destined to live a total of 69,000 years; had they been born in 1900 they would have had an expectancy of only 49,000 years; what will these 20,000 extra years be worth to them? Now it is announced for the first time that white women in the United States have at birth a life expectancy of 70.5 years. Medicine has decreased the fear of death, especially for the young; it has not and cannot produce immortality; it can only prolong the period of life. This prolongation of life is producing an aging population with new problems in the care of infirmities and in the further postponement of death from degenerative diseases. The final goal is not treatment but prevention, so that ultimately the costs of illness must decrease. Fundamental is health education so that informed people will avail themselves of what public health and medicine have to offer.

The American Medical Association is an organization of physicians whose chief concern is the care of the sick. Our progress depends on medical research and on the maintenance of a high quality of medical education. These objectives are emphasized in the charter and in the constitution of the Association. If anyone thinks that the medical profession is more concerned at this time with problems of social reorganization and problems of legislation than with problems of medical science, let him realize that these activities are necessary for improving and extending medical care and for preserving the characteristics that have made American medicine supreme in the world. "When the tumult and the shouting dies," our medical profession, relieved of this political burden, which is foreign to the purposes of medicine, will continue steadily to progress and go forward to new heights in the study and control of disease and in the advancement of public health.

MEDICAL INADEQUACIES

Among the expensive items in the costs of medical care, the chief concern is the hospital. More and more persons go to hospitals when ill, often because they have neither housing nor help which permit them to be sick at home. Moreover, many of the life-saving procedures developed by scientific medicine are immediately accessible only in hospitals. Years ago the patient with pneumonia was cared for at home, and, in the absence of modern effective remedies, too frequently he died. Now in the hospital he receives life-saving oxygen, antibiotics and transfusions and roentgenologic

President's address before the Ninety-Eighth Session of the American Medical Association, Atlantic City, N. J., June 7, 1949.

examination to determine the causes of sudden changes in his condition. And he lives instead of dying! These sometimes expensive procedures save lives but add to the cost of hospital care, although the total hospital days in any single illness are now usually less.

The ordinary expenditures of the hospital for labor, food and materials have grown large and constitute the chief hospital costs. In 1900 there were less than a thousand hospitals with approved standards; now there are over 6,000 registered hospitals with almost 1,500,000 beds, which in 1948 admitted close to 16,500,000 patients. But even this great increase in civilian hospital beds has not kept pace with the demand brought about by advancing methods of cure of disease, and by the rapid growth of voluntary hospital and medical care insurance. Hospital as well as housing construction was largely suspended during the war; since the termination of hostilities, costs of construction have risen precipitously, and funds previously considered adequate will build only a fraction of needed facilities. Extension of medical services is thus delayed by economic inflation.

Hospital boards are plagued by increased expenditures for necessary expansion, by decreased income from endowments and by decrease in new contributions, the former sources of which have been exhausted by taxation. Some hospitals are now prevented from utilizing their full quota of beds by limitation in nursing and service personnel. The demand for hospital beds can be relieved to some extent by provision in insurance policies for diagnostic procedures, such as roentgenologic examinations, without requiring hospitalization. Admittedly this presents difficulties in administration, but hospital costs can be lessened, and beds now occupied for diagnostic study made available for the more acutely sick.

Even for the patient at home, costs for nursing and medicines and necessary additional service accumulate a serious financial burden. Recent statistics indicate that costs for professional attention are relatively lower than other costs. These costs, which include increased wages to labor and increased prices of materials and food, are related to general inflation. They could be reduced in the present economic situation by reducing both the quality and quantity of hospital medical care, but this would not meet the needs or desires of the people. No doubt some saving could be accomplished, for both medicine and government, by continuous investigation as to possible economies and increased efficiency.

Some sparsely settled districts in the United States do not have medical care comparable to that available for most of the nation. Sociologic investigation is needed to determine the various cures for the deficiencies in such areas. Usually the area is economically poor, and could not support even modestly a qualified medical service. In few of these areas are there medical facilities such as laboratory and x-ray equipment necessary for an adequate service. The Hill-Burton bill, which was earnestly supported by the American Medical Association, is designed to supply diagnostic institutes, health centers and small hospitals, grouped geographically around larger hospital centers. Federal aid in the construction of these facilities is provided to the states where need is shown. Thus far governmental progress on this desirable project has been painfully slow. Establishment of these facilities will accelerate the redistribution of physicians to these areas. While this need is evident in many localities, its extent

should not be determined by a count of towns or counties without a physician. Recent studies of purchasing habits of people in this country by the Bureau of Medical Economic Research of the American Medical Association show that neither political boundaries nor geography determine the districts in which people purchase the necessities of life or the physicians whom they consult or even the hospitals to which they go.

The lack of physicians in certain regions may be corrected by a variety of procedures, determined by local conditions. Better distribution should follow the establishment of local diagnostic facilities such as are being developed under the Hill-Burton bill. Many communities by their own initiative have provided better medical facilities, and thus have secured better medical service. The use of subsidy and the development of group practice need further trial. In sparsely supplied communities, technics for transport of patients to medical centers are an immediate requirement.

VOLUNTARY HOSPITAL AND MEDICAL INSURANCE

Ordinary illnesses may dent but do not destroy the family budget; nevertheless, voluntary health protection should be placed in reach of all workers—and this is the goal of American medicine. Occasionally serious or catastrophic illness burdens the man of limited means with a sum that he is unable easily to meet. He must have protection, and this can best be furnished by the rapidly growing voluntary insurance system.

The voluntary hospital and medical insurance plans that have been developed grew slowly at first; a number of early plans failed because they were not based on reliable actuarial experience. With sound actuarial experience acquired during the experimental years, these plans have grown until now over 55,000,000 persons are covered by hospital insurance either by Blue Cross or private companies, and the numbers insured are increasing rapidly.

Besides the formal voluntary plans, data concerning which are readily available for summary, a vast amount of voluntary aid is given by local unofficial agencies of all kinds, including religious, fraternal and local projects, which number at least 25,000. Studies of this large source of assistance are now in progress. Certainly these agencies represent values which must not be destroyed.

Under the proposal for compulsory sickness insurance, the people of the United States are asked to discard a form of medical practice which, in spite of its recognized imperfections, has given them the best quality of medical care of any country, and to accept a scheme of governmentally regimented medicine which has resulted in deterioration of medical care wherever it has been established.

MEDICAL EDUCATION

Fundamental to every aspect of medical progress is the quality of medical education. In the last forty years, medical education in the United States has attained a high standard and has embodied in its advance the rapid increase in scientific knowledge. By persistent effort weaker medical schools have been strengthened, until we now have seventy-one acceptable four year schools and five more in process of organization. In addition, seven other schools offer the first two years of the medical course. Close cooperation with hospitals has been established to the great advantage of patients, students and the hospitals themselves.

Worldwide increase in medical knowledge has correspondingly increased educational requirements of the

medical student. The cost of medical education has been so multiplied that student fees meet but a small portion of the cost. Medical schools have suffered from lack of support due to oppressive taxation which syphons away private funds formerly available. Obviously medical schools must be aided financially either by private funds or government subsidy if they are to continue to supply enough physicians educated under a high standard to meet the needs of the nation. Regardless of the source of such aid the schools must be unhampered by political interference.

Recognizing that the time has now come to take stock again of medical education, and especially to inquire as to the source of the inordinately increased costs to universities of medical education, the Board of Trustees of the American Medical Association has authorized and supported a new survey to be made jointly by the Council on Medical Education and Hospitals and the Association of American Medical Colleges with the collaboration of the United States Public Health Service. In striving for ideals of which we approve, have we been wasteful of our resources? What has been the effect of federal grants for research on the universities and schools themselves? What will be the effects of such subsidies on national thinking? What will be required to increase the supply of physicians and at the same time maintain previous standards? If federal funds are used, what safeguards against political domination can be set up? The joint survey of medical education now under way should provide the answers to these questions and thus indicate the path for progress in the years to come.

ASSEMBLY LINES IN MEDICAL RESEARCH AND SERVICE

In every national plan in which government takes over the practice of medicine, uniformity interferes with personal incentive and initiative and diminishes the effectiveness of medical service. It substitutes a poor average for outstanding performance and limits progress. Uniformity, whether it concerns the administration of full medical care or of full employment, invokes the sovereign power of the state. Invoking these powers of government leads only to the destruction of personal liberty, the formation of blocs and the establishment of dictatorship. Proponents of government-controlled medicine disclaim any sweeping attack on democracy, but do admit that an extensive system of bureaucratic control will be necessary to make it work.

In many fields of community and national life uniformity of action may be economically necessary to make possible the utilization of science and discovery in raising standards of living. Mass production and the division of labor with the aid of machinery have enhanced the comforts of life and shortened the hours of labor. Assembly lines are at their best in dealing with inanimate objects; they fail miserably in dealing with sick human beings. They are excellent labor-saving devices profitably used to translate ideas which originated in laboratory research into finished products. Minor improvements are constantly being made in industrial assembly lines, but fundamental discovery has never come from this source alone.

Many fields of preventive medicine profit by the application of mass methods such as sanitation of water and food supplies, isolation and quarantine, mass immunization against contagious disease. These are procedures which the individual citizen does not perform for himself. The mass treatment of venereal disease

protects the community by supplying care to patients with what were formerly called social diseases. This care they cannot or will not apply for themselves.

But often the assembly line works danger to scientific research. Important fields of scientific research may require the joint efforts of many men. Such properly organized projects yield results of highest importance, but in our admiration for the scientific achievement we are prone to attribute chief praise to organization and to forget the original idea on which the project was founded. The assembly line is just as dangerous to research as it is to the sick patient.

SPECIALIZATION

The evolution of medicine, largely dependent on invention and discovery in other sciences, has been the basis for the continuing development of new medical specialties. Specialism was discussed early in meetings of this association; resolutions concerning specialists were introduced in 1854, and in 1866 specialism was the subject of the presidential address.

Certain physicians favored by opportunity or education or from personal preference became more expert in some departments of medicine, and their special abilities were recognized by their colleagues. Such men were regarded as specialists. To this increasing group of specialists other less well qualified men attached themselves; the protection of the public and of scientific medicine from poorly qualified men was one of the chief reasons for the establishment of the specialty boards. Another and more constructive reason was the encouragement of younger men better to qualify themselves for some division of medical practice, while still retaining general medical responsibility for their patients. The five or more years of additional study have added immeasurably to the quality of service which these men are able to supply to the sick. Today 5,000 to 7,000 younger physicians are studying advanced medical subjects in preparation for certification in internal medicine alone, while continuing their professional care of patients. The standards of medical practice all over this country are thus being raised, and the public receives medical care from better prepared physicians. To destroy this incentive to better quality of service to the public by nationalized medicine would be disastrous to both physicians and their patients.

The specialty boards themselves can increase their contribution to medical standards and service by a continuing reevaluation of their requirements in preparation for certification to meet community needs.

Some unforeseen difficulties have arisen. Hospitals desiring to establish an improved status have insisted on board certification as prerequisite to staff appointment. This may result on occasion in the exclusion of well qualified men. In choosing appointees for civil and military positions, officials in charge have taken the easy way of using the specialty board yardstick as the sole measure instead of considering the individual qualifications of candidates.

In some instances specialists themselves have selfishly contributed to the limitation of staff appointments. The general practitioner must be admitted to participation in the work of the hospital if the hospital is to render its full service to the community and the public. Indeed, general practice must be fully integrated into our system of medical service.

The correction of this difficulty where it exists can be accomplished easily by reverting to methods used

by governing boards of hospitals before specialty certification developed. The simple standard of ability, quality of performance and necessary service to the community, taking into consideration all available information, should govern staff appointments.

THE FAMILY DOCTOR

The "passing of the family doctor" is a phrase so often repeated that people have come to believe it. He has not "passed." There are more well trained, honest and understanding physicians devoted to the interests of their patients now than ever before. Most internists are "family doctors." If you inquire of many of the older "specialists," you will find that, while their expert ability is available and used by their colleagues and the public, their real interest and the larger part of their time is spent in helping and advising their own patients and families. They are the trusted advisors and receive the confidences of successive generations of their patients. One of the tragedies of nationalized medicine is the inevitable interference with this patient-physician relationship, by the interposition of governmental clerks and officials.

Unfortunately some of the younger physicians recently certified by specialty boards have assumed that, by establishing their technical qualifications, they have become disqualified, or have relieved themselves of responsibility, for the family practice of medicine. In this self estimate, some few of them may be right, but the majority will come to appreciate that the ideal practice of medicine includes not alone first class technical training and expertness with hands, eyes and ears, but in addition a sympathetic and spiritual urge for service to their fellow men. Here they will find one of the great enduring and compensating satisfactions in the practice of medicine.

SOCIALIZED MEDICINE MEANS SOCIALIZED AMERICA

Compulsory sickness insurance is socialized medicine notwithstanding the disclaimers of its advocates. A frank admission of this truth undoubtedly would raise questions embarrassing to those who advocate the plan; with tongue in cheek they camouflage socialism by using technics commonly employed by propagandists with revolutionary political programs. The proposed plan for governmental medicine, they say, will not change anything except the method of payment for services. Why then should it require 163 pages, as in the proposed law, and a confused organization of hundreds of councils, boards, committees and similar agencies just to collect and distribute money?

Illustrative of the perverse thinking of this group of advisors is the remark of one who in criticism of the Brookings Report said, "What you should rather do is to decide what you want to prove and then get the evidence to support it."

Is it possible that the heads of our government realize the serious position they have been led to assume? Are they aware that the advice which they have followed came from those who for years have been craftily planning a radical change in our democracy? Mr. Justice Brandeis warned: "The greatest dangers to liberty lurk in insidious encroachment by men of zeal, well meaning but without understanding." And Samuel Gompers as president of the American Federation of Labor said in 1916, "Look over all the world where you will and see those governments where the features of compulsory benevolence have been established, and you will find the initiative taken from the hearts of the people."

The great attainments of American medicine must not blind us to the necessity of correcting established faults in medical care. We must, however, adopt remedies, whether social or economic, which will lead toward cure and not toward chaos, toward increased progress and not toward destruction of values already attained.

Socialism asserts that constant emphasis on the "increasing misery of the masses" must be maintained so that the sense of unhappiness and desire for change may be perpetuated. It matters not that the standard of living has been progressively rising and that all have more comforts and better medical care than did our forefathers. People must be persuaded that they are worse off than they are; then they will revolt even against that which is good.

Statesmen, industrialists, labor, agriculture and the medical professions are all concerned in the provision of good medical care for the American people, but only if individual freedom and initiative can be guaranteed. Nationalized medicine will be followed by nationalized industry. Industrialists see the threat to free enterprise and progress. Labor leaders are beginning to realize that "free medical care" is not what they thought it was and that with socialization of medicine comes later socialization of industry and ultimately government ownership of business and facilities, with loss by labor of the gains of one hundred years. The farmer, always an independent thinker, dislikes being told what and how much he can raise, and how much he will receive for it. None of these groups would now vote for a managed economy or a collectivist state, and yet this is the real objective of those who are urging nationalized medicine on our governmental representatives.

Medicine and economics are intimately connected. Poor living conditions and poor food contribute not only to social unrest but also to poor health. The whole economy of the nation is dependent on the health of its people. In choosing a method of medical care which will accomplish our objective, we must have in mind the effect of the system of medical economy on the quality of medical service. Nor can we ignore the cost of any new system. The catastrophic effects of illness cannot be avoided by creating catastrophic bankruptcy.

Characteristic of America is individual initiative which has made America great. Always some forget that the individual in a democracy has a responsibility to the state; they assert that the state should care for all. Frequently they forget that they themselves furnish the funds that support the state. The government is the people and government funds are derived from the people by taxation, regardless of any pseudonym applied to the technic of collection.

The American people are urged to accept a federal monopoly of welfare. Citizens will lose individual initiative and responsibility characteristic of a democracy providing assurance of freedom, and they will become involuntary medical wards of the state.

Thus far standards of living and freedom in America are not approached by any other country. Let us oppose any efforts to substitute for this freedom a dubious socialistic program such as that now advocated by the proponents of nationalized medicine. We must be constantly mindful, with David Hume, that liberty of any kind is seldom lost all at once.

MYOCARDIAL INSUFFICIENCY

Mechanisms and Management with Data on a New and
Safer Mercurial DiureticGEORGE R. HERRMANN, M.D.
Galveston, Texas

The modern physician hopes to prevent the development of the symptoms and signs of myocardial insufficiency. The clinical evidences of potential or latent asymptomatic heart disease are certain reliable criteria.¹ The potentialities of the diagnosis should be recognized and a program for the postponement of heart failure inaugurated. It is desirable that one have a clear understanding and prompt interpretation of the derangements of the function which may insidiously put in an appearance in patients who had old healed heart lesions. Some knowledge of the mass of new human cardiologic data is indispensable. Many facts have been revealed in recent years by venous catheterization of the right atrium, ventricle and pulmonary artery, as devised by Forssmann.²

Critical consideration of the newer concepts is not only desirable but actually necessary for the scientific handling of patients. Some iconoclasts have taken the extreme view that congestive heart disease and circulatory failure result primarily from renal changes and disorders of salt and water metabolism. It must be admitted that edema, a most important manifestation of myocardial failure, is a product of deranged sodium excretion. The dissipation of edema, the objective of much of the treatment that is instituted in heart disease, is accomplished by increasing the output of sodium in the urine.

The fact remains that myocardial insufficiency begins in the heart muscle. The new data must be carefully appraised with this fact kept clearly in mind. The generally accepted conceptions of the functional origin of the symptoms and signs that accompany a weakening of the heart muscle support mainly the theory of back pressure failure. The evidence for a forward failure in some conditions is definite. The blood flow through the renal glomeruli as in other tissues is inadequate in either type and sodium is retained. The older ideas must be reviewed and reevaluated. Some revision is necessary as a result of recent discoveries. A broader and more comprehensive concept of the genesis of symptoms and signs of myocardial insufficiency has evolved.

CONCEPTS BASED ON INTERPRETATION OF VENOUS
CATHETERIZATION DATA

The recent great advance in the study of the circulation has been the result of the further development of the technic of venous catheterization of the right atrium, right ventricle and pulmonary artery. Cournand and his associates,³ Stead and Warren,⁴ McMichael and

Sharpey-Schafer,⁵ Merrill,⁶ Dexter and his co-workers⁷ and others have used the new methods in extensive studies of the circulation in human subjects. The method made possible the more accurate determination of cardiac output under varying conditions by the direct application of the Fick principle: Cardiac output equals the total oxygen consumption per minute divided by auricular-ventricular oxygen difference times 100. Stead and Warren⁴ found that the factors influencing cardiac output in heart disease are: (1) atrial pressure, (2) ventricular activity as controlled by the reflexes through the vagus, (3) peripheral resistance, (4) tissue requirements in the consummate vascular bed and (5) a factor of nervous imbalance brought about by sympathetic stimulation, by emotional stresses, or epinephrine or by autonomic suppression with atropine.

There has been reconfirmation of Starling's Law.⁸ The heart's diastolic volume is determined by the filling rate and pressure. The work of the heart equals the product of the stroke output and the mean pressure. The mechanical work accomplished by the ventricle is correlated with diastolic fiber length. As Starling and Visscher⁹ pointed out, the oxygen consumption increases with the length of fiber. As long as the oxygen supply keeps pace, the strength of the ventricular contraction and cardiac output will respond to increasing dilatation. Circulatory equilibrium is maintained, up to the critical diastolic volume and muscle stretch beyond which oxygenation lags and the ventricles fail to empty themselves. In myocardial dyskinesia basal relations of the cardiac output to the diastolic volume fail. The ability of the heart to do its job depends on the load of work it has to carry and the adequacy of the supply of oxygen and nutriment.

Inadequacy of the oxygen supply to the myocardium, especially the amount and availability of extra oxygen necessary for the accomplishment of added mechanical work, will cause myocardial efficiency to drop off, and a relative insufficiency in cardiac output develops. The ventricular cavities later dilate with an absolute decrease in cardiac output. Complex and partially effective compensatory mechanisms are called into play. McMichael and Sharpey-Schafer⁵ found evidence of an active venoconstriction to account for some of the increase or rise in venous pressure. The classic picture of congestive or backward heart failure, according to Harrison¹⁰ and Heyer with Harrison,¹¹ develops as the gradient of blood flow between the pulmonary and aortic systems drops off and as increased blood mass accumulates in the venous channels back of the heart. This backward or congestive failure often appears early in rheumatic carditis or coronary insufficiency, while there is still considerable myocardial reserve.

Circulatory or forward failure may develop in several conditions in which the arterial bed is widely dilated,

as in aortic regurgitation, severe anemia, hyperthyroidism and beriberi. In these conditions, the cardiac output in failure has been shown to be normal or actually increased, but still inadequate. The minute volume circulation is not greatly decreased; yet the blood flow actually provided to the tissues in the widely dilated bed may still be below the critical minimum required for the body as a whole. Sitting or standing decreases the cardiac output, while recumbency increases it.¹²

Clinical manifestations which are considered evidence of myocardial insufficiency have their origin in the failure of heart muscle in ventricular contraction adequately to supply the tissues with blood. There is thus a gradual or sudden dropping off of the ability of the heart to continue to increase, absolutely or relatively, the ventricular output in response to the demands. Merrill⁶ pointed out that at a certain critical level of cardiac output the blood flow falls below that necessary for the normal renal function of sodium excretion and for the adequate supply of enough oxygen to the tissues. There result sodium and water retention in the extracellular compartment, increased blood volume, venous congestion and reflex vasoconstriction. This is the picture of heart failure whether the inadequate renal blood flow is due to absolute or relatively inadequate cardiac output.

CONGESTIVE BACKWARD PRESSURE AND CIRCULATORY FORWARD PROPULSION FAILURE

The theory of backward pressure congestive failure is easily visualized.¹⁰ The rate of development determines the extent and character of the clinical symptoms and signs. In the very suddenly developing acute insufficiency or left ventricular failure, extreme dyspnea and orthopnea develops and acute pulmonary edema promptly appears in the lungs. In the chronic insidious type, besides the lung congestion, the right ventricle also fails, with engorgement of the liver and ascites accumulating very late and producing dropsy in the dependent parts. Chronic backward failure, the traditional congestive failure, with low cardiac output and low pulse pressure, is found in myocarditis of coronary atherosclerotic origin, myocardial infarction, rheumatic myocarditis, diastolic hypertension, hypothyroidism, heart tamponade and pericardial constriction.

Forward, or circulatory, failure with normal or supernormal yet inadequate performance of the left ventricle has been demonstrated. Acute forward circulatory failure occurs in cardiac standstill, extreme bradycardia or tachycardia, shock and hemorrhage. Chronic circulatory forward failure of the type with high systolic cardiac output and high pulse pressure, yet insufficient minute volume of blood flow, occurs in rheumatic or syphilitic aortic regurgitations, systolic hypertension, hyperthyroidism, arteriovenous shunt, congenital lesions, anemia and beriberi.

DISORDERS OF SALT AND WATER METABOLISM

Many of the symptoms associated with heart failure have been shown in recent years to be more closely associated with disturbances of salt and water metabolism. Apparently the circulation in the kidney is most sensitive to changes in the general circulation, and renal blood flow is the first to be affected by relative

or absolute decrease in cardiac output.⁶ The kidneys promptly effect a shift in blood volume flow and secondarily in salt and water metabolism. The urinary output may be reduced to a fifth of normal, and yet there is specifically only sodium retention.

The secondary constriction of the efferent arteries may insure a normal glomerular filtration of sodium but not of sodium excretion, since tubular reabsorption of sodium has become supernormal. The kidneys and tissues seem to hold tenaciously to sodium in patients with congestive failure.

The reabsorption of sodium in the renal tubules may be greatly enhanced, incident to an excess of anti-diuretic hormone, which the slow circulation in the pituitary may have called forth. The retention of the sodium has been held responsible for the increased blood volume and the venous pressure rise.

Warren and Stead,¹³ in 1944, reestablished circulatory equilibrium by treatment of dehydrated patients in congestive failure with mercurial diuretics, and thus these patients, on the verge of heart failure (untreated), showed increase in body weight preceding the rise in the venous pressure. Warren and Stead¹³ concluded that the edema developed because the kidneys did not excrete salt and water in the normal manner and that blood volume increase was the cause for venous pressure rise. Grant and Reischman,¹⁴ in 1946, and Heyer and Harrison¹⁵ had patients with chronic atrial fibrillation under perfect control with digitalis. They found that on withdrawal of the digitalis from these patients there followed promptly a rise in the venous pressure preceding any increase in weight, and they concluded that venous pressure rise preceded edema. Myocardial weakness may well create these disturbances in function.

The study of salt and water metabolism by Burch and Reaser,¹⁵ using the isotope sodium 22, revealed a sharp ninetyfold retention of Na²² in cases of heart failure. They found that in a cardiac patient 50 per cent of Na²² was eliminated in about twelve weeks, while in the normal controls the same amount was eliminated in twelve days. They demonstrated that mercurial diuretics increased the Na²² output twenty-four fold and the chloride output concomitantly followed. The sodium and the water in the extracellular compartment and plasma definitely showed a concordant rise and fall. It had been reported by Calvin¹⁶ that the plasma protein content of the blood mass actually increased in hemodilution and that blood serum proteins and albumin were added from the tissues in hydremia. Among patients with congestive heart failure and edema were found some in whom oligoalbuminemia was absolute as well as relative, probably as a result of hepatic damage, and in these the low albumin level of the serum contributed to the edema.¹⁷

PHARMACODYNAMICS OF CARDIAC GLYCOSIDES IN
CONGESTIVE HEART FAILURE

Digitalis shortens the cardiac systole and lengthens diastole within four hours after administration by mouth. There is thus produced increased myocardial efficiency and increased cardiac output, especially with slowing of the ventricular rate in atrial fibrillation. McMichael and Sharpey-Shafer^{5a} suggested that venoconstriction be released by digitalis. Venous return and arterial pressure may be decreased in heart failure and subsequent venodilatation enhances the return flow. McMichael^{5b} maintained that if the heart is being filled at pressure above the optimal, digitalis may further increase rather than diminish the cardiac output.

In patients with circulatory failure and increased output due to hyperthyroidism, aortic syphilis with free aortic regurgitation, arteriovenous fistula, anemia or beriberi, symptoms are usually not conspicuous until the conditions are far advanced. When decompensation does develop it persists even after the myocardial insufficiency is rigorously treated, as the cause cannot often be removed. In such cases, the need for minute volume flow, for the whole body or a large area, produces a reduction in venous filling which cannot be compensated for. A shock state may possibly develop, and the brain and the heart may be irrevocably damaged as a result of the demand and diversion of blood flow to other tissues.

In patients with congestive heart failure and decreased cardiac output as a result of myocarditis from acute rheumatic fever, coronary artery or hypertensive heart disease with tachycardia and disorders of mechanisms, the symptoms are promptly relieved by digitalization. In acute myocardial infarction, mitral stenosis and tachycardia, and especially in atrial fibrillation, congestive failure is usually precipitated early while apparently the myocardium has considerable reserve. The response to digitalis is usually prompt and the cardiac output rises to the point where the circulatory equilibrium is reestablished.

EMERGENCY AND CARDIAC THERAPY

In acute left ventricular failure and pulmonary edema, there is need for emergency treatment. Death may occur from anoxia, as in drowning. Oxygen under 4 to 6 cm. of water pressure should be administered until the cyanosis clears. Trapping venous blood in all four extremities with tourniquets or actual phlebotomy may halt the paroxysm. Morphine, sulfate, 11 mg. ($\frac{1}{6}$ grain), and atrophine, 1 mg. ($\frac{1}{65}$ grain) usually allay anxiety, relax spasm and suppress excessive secretion of mucus. Meperidine hydrochloride, 100 mg., is considered safer by some observers. It is to be remembered that narcotics and barbiturates have some antidiuretic action.

Cardiac tonics intravenously, as ouabain (0.25 mg.), digitoxin (1 mg.) or lanatosid C (0.8 mg.), may be given intravenously if one can be certain that the patient has had no digitalis within two weeks. In persisting pulmonary edema one may give a hypertonic infusion of 50 cc. of 50 per cent dextrose to which has been added 0.5 Gm. of aminophylline and 0.5 Gm. of ascorbic acid after giving a mercurial diuretic, as 40 mg. of thimerin® (the disodium salt of N [gamma-carboxymethyl-mercaptomercuri-beta-methoxy] propyl camphoramic acid) subcutaneously.

Normal Sinoatrial Cardiac Mechanism.—Normal sinoatrial cardiac mechanism is most conservative. It is desirable to maintain or reestablish sinoatrial rhythm if disorders of the cardiac mechanism persist. In the cases of atrial fibrillation and failure, adequate digitalization is in order. If, after digitalization, the failure persists, one is justified in undertaking to restore the normal mechanism with quinidine sulfate.

Rest.—Morphine judiciously used is a great boon to all patients with heart failure, as it reduces the exhausting respiratory effort of dyspnea decubitus. Addiction, however, is easily induced, and it must be guarded against. Adequate rest is necessary to improve the myocardial efficiency and the relief of pulmonary congestion. One should decrease all physical strain, by making the patient as comfortable as possible, which contributes definitely to the reestablishment of circulatory equilibrium.

The more refractory cases of congestive heart failure may not be relieved satisfactorily and edema may persist, in spite of rest, diet and digitalization, and sinoatrial rhythm. The physician may resort to the use of coronary vasodilators to improve myocardial function and diuretics to remove edema and improve circulatory efficiency. The myocardial function may not be improved adequately by the vasodilating effects of nicotinic acid and papaverine and the older favorites, orally administered xanthine diuretics, as theobromin®, theophylline and aminophylline. The potent mercurial diuretics, especially those combined with the theophyllines, must usually be used. The newer one, containing the sulfhydryl radical, may be the one of choice as it is less toxic.

A NEW LESS TOXIC, MERCURIAL DIURETIC

Burch and Reaser¹⁵ demonstrated that sodium output in the urine was increased seventy-five fold as a result of mercurial xanthine diuretics. These drugs are generally accepted as the first rank preparations for the mobilization of sodium and the drugs of choice for the patient with intractable edema. Novasurol® (merbaphen) was soon found to be too toxic. Salyrgan® (mersalyl) was then produced and found to be less toxic. It had to be given intravenously and was irritating and potentially toxic. It occasionally produced necrosis of the renal tubular epithelium. The Hungarians^{17b} added acid theophylline to neutralize the excessive alkalinity of the mersalyl and found that potency was enhanced.

My co-workers and I^{17a} had found that mersalyl produced diuresis by decreased tubular reabsorption, while aminophylline increased glomerular filtration and neutralized excessive alkalinity. We therefore combined the two and observed augmented diuresis and no more instances of destruction of the epithelium or renal tubules. Mersalyl and theophylline (salyrgan® with theophylline) or mercurophylline (mercuzanthin®) have been widely used with occasionally evidence of toxicity. Other less toxic combinations of mercurials were sought. At least two instances of fatal ventricular fibrillation were electrocardiographically recorded during and following the intravenous injection of another mercurial diuretic. Mersalyl with theophylline and mercurophylline were too irritating to be injected in any way except deep in the muscle with local anesthesia or intravenously. Meralluride sodium (mercuhydrin®

sodium), a urea succinyl mercurial-theophylline combination, was demonstrated to be a potent diuretic and less toxic by Chapman and Shaffer. It was found to be well tolerated, causing little, if any, pain when injected intramuscularly.

The emphasis, however, has now been shifted from potency to the toxicity factors in mercurial diuretics. Lehman¹⁸ combined MT 6, chemically similar to mercurophylline except that the sulphydryl replaces theophylline, with sodium thioglycollate and found that the sulfur had profoundly decreased the toxicity and irritating effects of the mercurial. He noted a tremendous increase in tolerance of the new MT 6, mercaptomercurial, when it was compared with the older diuretics. This combination is theoretically an ideal and safe mercurial diuretic. Lehman¹⁸ found that thiomerein[®] was 160 times less toxic than meralluride sodium. It could be injected subcutaneously without producing any significant pain or irritation. This marks a definite forward step in the development of organic mercurial diuretics. It might be well for one to test every patient for hypersensitivity to mercury by injecting subcu-

pitating factors, alleviation of the perpetuating factors and alteration of the predisposing factors in so far as is possible. Recumbency allows blood and edema fluid to flow into the chest and waterlog the lungs; therefore, the sitting upright posture is preferable.

Rest in the position most comfortable to the patient removes some of the demands on the circulation. The physical strain of severe dyspnea may be relieved by oxygen (mask or tent) and responds to the hypodermic injection of morphine sulfate (11 to 16 mg.). In cardiac asthma of acute left ventricular failure meperidine hydrochloride, 50 to 100 mg., given intravenously may be safer than morphine.

Diets low in sodium and with acid ash, as Karrell's daily ration of 4 glasses of milk with 8 slices of dry, salt-free, toasted bread, often helps to start diuresis. Newburgh,¹⁹ Schroeder,²⁰ Schemm²¹ and Wheeler, Bridges and White²² have worked out more elaborate low sodium, neutral or acid ash regimens, with free fluid intake. Water, dilute hydrochloric acid, or acid salts as ammonium chloride are often helpful in promoting diuresis. Barbiturates and narcotics have some antidiuretic effect.

The sodium storage may be reduced by sharp curtailment of intake. A sodium-free diet is difficult to prepare and even a low salt diet with salt substitutes is not easily maintained. It is often most practical to insist on only moderate restrictions and the judicious use of the mercurial diuretics rather than enforce an inadequate diet. One may reduce the sodium chloride content of the patient at regular intervals with mercurial diuretics.

Water Intake.—Schemm²¹ advocated forced fluids by mouth and 5 per cent dextrose solution slowly given by vein in amounts up to 4 liters a day. I have not had much success with this regimen; yet Schemm emphasized the importance of and need for adequate fluid intake. One should administer distilled water in quantity to satisfy normal needs, namely, 2,500 to 3,500 cc. The amounts must be increased in cases of fever or in the patient with low concentrating ability of the kidney. It is admitted that cellular dehydration may be present in the brine in cardiac edema. However, forcing fluids by giving intravenously 5 per cent dextrose in a patient with congestive heart failure is not without danger. It may be accomplished with great care by a very slow drip method. I have seen several instances of acute left ventricular heart failure following intravenous injection of 5 per cent dextrose solution in 2 to 4 liter amounts. The retained sodium determines the volume of the fluid retained in the body.

Diuretics.—Diuretics, notably the organic mercurials combined with xanthines, and now with sulphydryl, have been shown to increase tremendously the urinary flow and sodium output. Pulmonary as well as subcutaneous edema is promptly dissipated, and as a result the patient feels much better, his breathing becomes

Summary of Clinical Diuretic Results

Drug	No. of Cases	Total Urine Cc. First Day	Average Increase in Output of Urine, Percentage			
			First Day	Second Day	Third Day	Total

taneously 0.25 cc. to 0.5 cc. of thiomerein[®] before giving the 2 cc. dose that contains 78 mg. of mercury.

Thiomerein[®] was submitted to me with a grant for further experimental study and extensive clinical trial. The New York University group in Bellevue Hospital had obtained very encouraging results, as my co-workers and I have, but it will take extensive studies before the ultimate evaluation is made. I have observed few and minimal reactions from thiomerein[®] even when given intravenously, in 20 cardiac patients, and adequate diuresis was produced with the new drug given subcutaneously to 135 patients. The results shown in the table were obtained with this preparation, given under my supervision, by Dr. John W. Chriss, Dr. Milton R. Hejtmancik and Dr. Paul M. Sims. The potency and low toxicity warrant continued extensive use of the thiomerein[®] to establish its ultimate safety factors, especially in the rare patients whose heart muscle is hypersensitive to mercury.

SUMMARY AND ADDITIONAL MATERIAL ON THERAPEUTIC PROCEDURES IN MYOCARDIAL INSUFFICIENCY

The modern treatment of a patient with heart disease calls for the prevention of potential failure and prompt relief of the first disturbing or ominous symptoms. Steps are taken to guard against and remove the pre-

easier and he feels stronger. It must not be forgotten that potent mercurial diuretics may produce confusing symptoms of primary salt depletion, especially in patients on low sodium diets.

Small doses of a mercurial diuretic will often interrupt a chain of nightly paroxysms of dyspnea. I am not yet ready to advocate repeated full doses given intravenously or intramuscularly (usually 2 cc., 78 mg.) of mercurial diuretics twice daily until the ideal weight is reached. I fear that the mercury may be accumulated and be toxic to the heart and kidneys. I have seen anuria produced by physicians who had neglected to examine the urine before injection of the mercurial. The new mercurial sulfydryl thiomerein® is well tolerated subcutaneously, is least toxic and therefore safer and adequately effective.

Digitalis.—Digitalis therapy improves the myocardial tone and increases cardiac output and therefore warrants consideration. In acute left ventricular failure, ouabain (strophanthin) 0.25 mg. given intramuscularly is probably safer than any digitalis preparation, even digitoxin, in a dose of 1 mg. Digitalis is most useful in the control of mechanism disorders like atrial fibrillation. Digitalization will usually relieve exertional and decubital dyspnea.

Some modern experimentalists have concluded that the use of digitalis is obsolete and that digitalization may aggravate the situation if the cardiac output is normal and in full response to the diastolic stretch. When this relationship fails, the effect of digitalis is limited at best, as the cause persists. Some feel that digitalis maintains cardiac tone and delays dilatation and hypertrophy and should be started as soon as a diagnosis of "heart disease" is established. Proofs of these contentions have not yet been established.

CONCLUSIONS

I cannot agree with those who argue against the need for digitalization when the rhythm is regular. Others feel that strict adherence to a low sodium regimen is all that is necessary to prevent edema formation.²² A very low sodium diet is most unpalatable and difficult for many patients to maintain.

Since the edema can be cleared by mercurial diuretics which may be repeated at intervals, it would seem practical to use this means of getting rid of accumulated sodium. Thiomerein®, given subcutaneously, is a practical and safe diuretic for this purpose.

I believe that each of these methods has a place in the therapy of myocardial insufficiency, as has been discussed in detail in the previous paragraphs. Sometimes one method may be employed first, sometimes another, and again any combination may be instituted at the same time. In urgent situations all methods are applied as soon as possible, and generally the judicious use of the combined methods brings about most satisfactory results.

Radioactive Digitalis.—Instead of irradiating digitalis, we are now getting it in a radioactive form. In airtight glass jars, foxglove is being grown in an atmosphere of radioactive carbon dioxide. While only small quantities of this radioactive digitalis obtained in this fashion have yet been produced, it is now being studied in animals in Atomic Energy Commission laboratories, and we hope will bring further understanding of the manner in which the heart operates.—From an address by David E. Lilienthal, Chairman, Atomic Energy Commission, before the American College of Physicians, New York, March 31, 1949.

SOME FACTORS INFLUENCING RESPONSE OF CANCER TO RADIATION

CONSTANCE A. P. WOOD, M.R.C.S.(Eng.)
London, England

During the past two decades great advances have been made in the treatment of cancer by radiation. These advances are largely the result of physical researches.

In Great Britain, the greatest importance has been attached to the close collaboration of radiotherapist and physicist. In all radiotherapy centers this partnership has for many years been regarded as essential to the efficient carrying out of the patient's treatment. Much time has been devoted to the establishment of methods of accurate dosage measurement for all types of radiation therapy, whether it be external irradiation from a roentgen or radium beam or local irradiation by radium needling or applicators. Whichever of these types of treatment is used, the dose delivered to the tumor is recorded in roentgens in the tissues at the site of the disease. These methods of accurate dosage measurement have done much toward placing the radiation treatment of cancer on a scientific basis; they enable an accurate comparison to be made of the techniques used and the results obtained in different centers throughout the world. A description of these technical methods is not within the scope of this paper. Other speakers have dealt with the measurement of tumor dose in interstitial radiation, and I have described elsewhere methods devised for the measurement of tumor dose in external radiation by a roentgen or radium beam. It is sufficient here to say that methods have been devised for accurately directing the beam of radiation and for estimating the dosage delivered to the tumor. Not only can one estimate the dosage at selected points in the tumor, glands and skin by instruments such as Green's measuring caliper, but, with a new instrument, the dose contour finder designed by Flanders, one can obtain a three dimensional picture of the dosage distribution throughout the whole of the cancer-bearing area. Such methods are of the greatest assistance in the attempt to deliver an equalized dose throughout the whole volume of tissue treated and are of inestimable value in guiding the radiotherapist in his prescription of treatment. The dosage necessary to destroy a growth is not far removed from that which will produce radionecrosis. Without careful planning of the treatment, outlying fringes may easily receive too little radiation, while regions in the center or at the junctions of the fields of radiation are liable to suffer from overdosage. We are all only too familiar with the unhappy sequelae of overdosage in the form of bone and cartilage necrosis. These methods of accurate dosage measurement and control have greatly reduced the number of such cases of radiation necrosis.

Methods have also been devised for estimation of the dose delivered to parts of the body other than the tumor—the so-called integral dose—and by this means severe constitutional reactions can be avoided.

With these improved methods of dosage estimation and control, the part played by radiotherapy in the treatment of malignant disease is considerable. Elsewhere I have spoken of the value of palliative treatment in cases in which the disease is too advanced to justify any expectation of a permanent cure.

²²Read before the Section on Radiology at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 24, 1948.

In addition to their assistance in carrying out the patient's treatment, these technical methods have helped in many ways. There are three separate instances of this in my own work which I should like to mention. Firstly, in routine radiotherapy departments the radiation most commonly used is that derived from a 200 kilovolt roentgen ray set; this gives a much longer

Fig. 2.—Graph of cell counts in a tumor showing a favorable response to radiation. The horizontal row of figures at the bottom represents time in days. The vertical column of figures at the left shows cell counts per hundred cubic centimeters.

wavelength than that derived from radium gamma rays which are equivalent to 1,700,000 volt roentgen rays. It was thought possible that the shorter wavelength radiation from radium might have a different biologic effect from that of 200 kilovolt roentgen rays. In order to determine, therefore, whether there was any difference in the response of tumors to the two kinds of wavelength, an experimental comparison between a radium beam and a 200 kilovolt roentgen ray beam in the treatment of cancer of the mouth and throat has been carried out at the Medical Research Council's Radiotherapeutic Research Unit, London.¹ The experiment was very time consuming. The results have been assessed by a

Fig. 2.—Graph of cell counts in a tumor showing a favorable response to radiation. The horizontal row of figures at the bottom represents time in days. The vertical column of figures at the left shows cell counts per hundred cubic centimeters.

new statistical method developed by Boag for estimating from interim clinical results the proportion of patients cured. The results do not indicate that the wavelength of radiation per se has any significant effect on clinical results. With still higher voltage roentgen rays one

cannot therefore confidently expect any improvement in clinical results due solely to the shorter wavelength of the radiation. The great advantage that can be expected from the higher voltages is not a different biologic effect but a greatly improved dosage distribution within the patient, which is possible with higher voltage roentgen rays. It will be appreciated that without the assistance of accurate dosage measurements, it would not have been possible to carry out this experiment with an accuracy sufficient to enable any confidence to be placed in the results obtained.

Secondly, my colleagues and I were able with the help of these technical methods to insure that in the treatment in a series of cases of mouth cancer, a comparable dose of radiation was delivered to both primary tumor and glands. It was thus possible to compare their relative radiosensitivity. Contrary to the opinion generally held, we found that when treated with comparable dosage the glands offer no greater resistance to radiation than does the primary tumor.¹ It would appear, therefore, that one must search for some other explanation to account for the higher mortality rate universally found in patients with lymph node involvement.

Fig. 3.—Photomicrograph before treatment of a tumor which showed a favorable response to radiation.

Thirdly, these technical methods have made it possible for a particular technic of treatment to be accurately repeated; they have enabled us to be certain that precisely the same dosage is being delivered to patients having similar lesions. By this means, we have found that epitheliomas in the mouth similar in clinical and microscopic appearance, when treated by precisely the same technic, do not necessarily give the same response to radiation.

There is not time to enlarge on the significance of these conclusions here. To one, at least, I wish to refer again later in this paper. The point I wish to stress now is that it would not have been possible to arrive at such conclusions without the assistance of methods of accurate dosage measurement.

In any future work with supervoltage roentgen rays or neutrons the physical control of dosage becomes increasingly important, and it is therefore essential that these technical methods continue to be developed. From a comparison of the clinical results of radiation treatment in recent years with those obtained some years ago, it has become clear, however, that the great advances which have been made in the technic of treatment have not resulted in a correspondingly large

1. Wood, C. A. P., and Boag, J. W.: Researches in the Radiotherapy of Oral Cancer, Medical Research Council, Special Report Series, London, His Majesty's Stationery Office, to be published.

increase in the proportion of patients cured. These improvements in technic were an essential preliminary step, and I have attempted to show the importance of the role they have played. I would emphasize, however, that it is in general no longer possible to ascribe failures in radiotherapy to an inability to deliver the predetermined dose of radiation to the tumor. It would appear that there are other factors than physical dosage which have a fundamental effect on the response of tumors to radiation.

A new method of approach is indicated, and the problem has become one of radiobiology. In an attempt to discover what biologic factors determine a satisfactory response to radiation an investigation has been carried out in the Medical Research Council's Radiotherapeutic Research Unit, London, in collaboration with Spear and Glucksmann of the Strangeways Laboratory, Cambridge.¹ This work deals with only one aspect of the whole problem, but it is, I think, of sufficient interest to warrant my giving the main outline of the work and the conclusions to be drawn from it.

In a series of patients treated by radiation for epitheliomas of the oral cavity a preradiation biopsy specimen

Fig. 4.—Photomicrograph on the fifth day of treatment, after 1,000 r to a tumor which showed a favorable response to radiation.

was taken in each case from the growing edge of the tumor, and then serial biopsies were made throughout the course of treatment. Cell counts were then made by Spear and Glucksmann in comparable areas of these biopsies.

The diagram (fig. 1) from the Strangeways Laboratory depicts the two types of cells in epithelial growths. The viable cells are the resting and mitotic cells—the nonviable are the differentiating and degenerating cells. The object of radiation is to convert viable into nonviable cells. This is done, firstly, by making the resting cells incapable of further cell division either by causing them to differentiate and so become sterile or by causing their immediate breakdown into degenerate cells and, secondly, by causing the breakdown of mitotic cells into degenerate cells, so preventing further cell division. These changes developing in individual tumors as a result of radiation may be followed by cell counts in serial biopsies and expressed in the form of graphs.

Figure 2 shows the response of a tumor in which radiation promoted progressive increase of differentiation and final disappearance of all the resting and mitotic cells, that is, of all viable cells so indicating the

destruction of the tumor tissue and final disappearance of growth. This type of graph is typical of a favorable response to treatment.

Figures 3, 4 and 5 are photomicrographs of the tumor depicted graphically in figure 2. The first biopsy specimen (fig. 3), taken before treatment, shows resting cells and mitotic cells.

Fig. 5.—Photomicrograph on the twelfth day of treatment, after 2,000 r to a tumor which showed a favorable response to radiation.

The second biopsy specimen (fig. 4), taken on the fifth day of treatment, after 1,000 r had been given, shows an increase in the degree of differentiation. The proportion of the resting and mitotic cells has decreased, while the differentiating cells have increased. The degenerating cells have also increased in size, and two horny pearls are visible.

The third biopsy specimen (fig. 5) taken on the twelfth day of treatment, after 2,000 r had been given, shows still further differentiation. The resting cells have now almost all disappeared and have been replaced by keratinizing, that is, differentiating, cells. These are shown with darkly stained cytoplasm. They are on their way to cell death and will in due course be cast off as cell debris. The clinical end result in this case is in agreement with the histologic prognosis. The

Fig. 6.—Graph of cell counts in a tumor showing an unfavorable response to radiation. The horizontal row of figures at the bottom shows time in days, and the vertical column of figures at the left shows cell counts per hundred cubic centimeters.

patient had an extensive epithelioma of the soft palate just extending onto the hard palate. He also had lymph node involvement in the neck. After radiation both primary growth and enlargement of the nodes disappeared, and he has remained symptom free for five years, without any recurrence of the growth, at the time of writing.

Figure 6 shows the response of a tumor in which there are only minor variations in the cell counts, indicating the persistent growth of the tumor and an unsatisfactory response to radiation.

Figures 7, 8 and 9 are photomicrographs of the tumor depicted graphically in figure 6. The biopsy

Fig. 7.—Photomicrograph before treatment of a tumor showing an unfavorable response to radiation.

specimen shows a persistence of actively growing tumor tissue, and the only noticeable change is a temporary increase in cell size after 1,000 r had been given.

The first biopsy specimen (fig. 7) was taken before treatment began. The second biopsy specimen (fig. 8) was taken after 1,000 r had been given, five days after the beginning of treatment; the third biopsy specimen (fig. 9) was taken after 2,000 r had been given, ten days after the beginning of treatment. Looking at any of these biopsy specimens, every pathologist would give an actively growing squamous cell population—a very slight decrease in mitotic activity

Fig. 8.—Photomicrograph on the fifth day of treatment, after 1,000 r to a tumor showing an unfavorable response to radiation.

and an equally slight increase in the incidence of degenerating cells.

The clinical end result in this patient is again in agreement with the histologic prognosis. This patient had an extensive ulcerating epithelioma involving the right tonsil. No glands were present. The growth

never responded to radiation, and the patient died within eleven months of starting treatment.

The biopsy observations can be regarded as typical for the whole tumor only if the dose delivered to the biopsy site is comparable with that given to other parts of the tumor.

Spear and Glucksmann found that by these cell counts a prognosis could be made for the malignant tissue in the treated area and that the eventual response of individual tumors could be foretold.

We found that in our series of carcinoma of the oral cavity an accurate prognosis was made concerning the end clinical result in the large majority of cases. In a series of 90 cases there was agreement between the histologic prognosis foretold by these cell counts and the subsequent clinical result in 75 cases. It will be seen that in only 1 case in which the histologic prognosis was favorable was the clinical result unfavorable. This is highly significant, and a statistical analysis shows that, if there were no correlation between prognosis and clinical result, agreement such as this would be obtained merely by chance once only in 100,000,000 trials.

Fig. 9.—Photomicrograph on the tenth day of treatment, after 2,000 r to a tumor showing an unfavorable response to radiation.

These cell counts have led to the conclusion that an increase following radiation in the proportion of differentiating cells distinguishes those epitheliomas which will respond favorably to radiation from those failing to respond. The promotion of differentiation, therefore, appears to be an important factor in the sterilization of tumor tissue. This increase in differentiation takes place most frequently, but not always, in tumors of the differentiating type, though anaplastic tumors do sometimes differentiate as a result of radiation treatment.

The capacity to respond to radiation by differentiation is more likely to be present in the differentiating type of tumor than in the anaplastic; but, as Glucksmann pointed out, it does happen that in some differentiating tumors this capacity appears to have reached its full limits while in some anaplastic tumors there is a latent capacity for differentiation.

The promotion of differentiation by radiation depends on an inherent capacity in the tumor cells, and such changes in individual tumors can be recognized only by examination of serial biopsy specimens. I have already made reference to the fact that we found that

two growths which appear similar both clinically and histologically, when treated by precisely the same radiation technic, do not necessarily give the same response. This difference in response would be explained if the cells of one tumor possessed the capacity to differentiate after radiation, while in the other tumor this capacity was lacking.

It has for many years been a well recognized fact that the highly differentiating epitheliomas of the skin give far better clinical results to radiation treatment than epitheliomas arising in such sites as mouth and throat. These better results in the cutaneous tumors are not due to any refinements in radiotherapeutic technic, but must be ascribed to difference in the incidence in these two sites of tumors which respond to radiotherapy by differentiation.

Inability to cause differentiation is one cause of failure of radiation treatment. These cell counts indicate that another cause may be the persistence of precancerous lesions.

Figure 11 shows a stretch of untreated epithelium of the tongue with both normal and precancerous areas.

		HISTOLOGIC PROGNOSIS		TOTALS
		F	U	
CLINICAL RESULT OF ORIGINAL TREATMENT	F	16	14	30
	U	1	59	60
TOTALS		17	73	90

in the basal layer. In the precancerous area the small darkly stained resting cells have increased to four or five basal layers. The resting cells have relatively little cytoplasm and a relatively large nucleus; this is why they are stained darker than the larger differentiating cells which have relatively more cytoplasm.

The main characteristic of the precancerous change consists in a relative increase in the number of resting and dividing cells, i. e., the viable cells, and a relative decrease in the number of differentiating cells. The difference in the relative proportions of resting to differentiating cells for normal and precancerous areas is well illustrated in this figure. The cell counts have shown that a precancerous area near a cancer included in the treatment field may respond differently to radiation from the area of frank malignancy. It was found that in some patients it is possible to sterilize the area of frank malignancy while the precancerous lesion persisted in spite of radiation, and subsequently a new tumor (wrongly called a recurrence) developed in the treated area.

Figure 12 shows the reaction to 1,000 r of a normal stretch of epithelium in a carcinoma of the tonsil. The basal layer of the epithelium is denuded of cells which have degenerated and which are still visible as degenerate cells or marked by gaps. Only a few resting cells remain.

Fig. 11.—Photomicrograph showing a stretch of untreated epithelium of the tongue with both normal and precancerous areas.

Figure 13 shows a precancerous stretch of epithelium after the same time, five days, and after the same dose, 1,000 r. Here the basal layer is complete, one cell layer thick and composed of resting and mitotic cells.

Fig. 12.—Normal stretch of epithelium after administration of 1,000 r.

Figure 14 shows a precancerous area of the epithelium on the fifteenth day and taken after 2,000 r had been administered. The basal stratum is now at least three cell layers thick and composed of resting and mitotic cells. There are a few degenerate cells at the border between the basal layer and the keratin-

ized layers. These biopsies illustrate that the mitotic activity may persist in a treated precancerous lesion and that in such an area, even with radiation treatment, an increase in the proportion of viable resting cells may develop. Thus, in some patients, although the response of the malignant tissue is favorable, as indi-

It is not possible for the end clinical result of radiation on a tumor to be judged by the immediate macroscopic effect, such as shrinkage in size of the tumor, but by these cell counts it is possible to judge what the end clinical result will be.

CONCLUSION

The work of Spear and Glucksmann stresses the importance of tumor type. The problems of nondifferentiating epitheliomas and precancerous lesions are subjects for future research. It appears as if entirely different treatment may be necessary for different types of epitheliomas arising in the same site and that further improvements in physical technic are unlikely to bring about better results without due regard to tumor biology. It is felt that advancement in knowledge of the fundamentals of radiobiology leading to a better understanding of the action of radiation on the living cell offers the greatest possibility of any improvements in the radiation treatment of malignant disease.

ABSTRACT OF DISCUSSION

DR. DOUGLAS QUICK, New York: Dr. Wood has been devoted to improving the accuracy of therapy by irradiation. Her approach has been methodical and carefully planned, first by direction, then by localization, next by calculations of exact amounts at various points of distribution and now an attempted approach through radiobiologic channels. As a clinician long associated with radium, I have never been quite able to accept the accumulating evidence in favor of no variation in tissue effect with varying qualities of radiation. Dr. Wood comes nearer than anyone else to convincing me that there is no difference in effect between roentgen rays and the gamma rays of radium, other than a quantitative one—almost, but not quite. However, I cannot accept Dr. Wood's second assumption, namely, that the primary growth and its metastatic node show equal response to equal quantities of radiation. My statement presumes to oppose pure science—that is, clinical measurements—by opinion. However, careful observations over a period of years and under many and varying conditions are of some value. It is my experience that the metastatic lymph node is regularly more resistant to irradiation than is its parent or primary growth. I see nothing illogical in the fact that there is a higher mortality rate in patients with metastatic nodes than in those without them. It is not a question of radiation at all. It is because that particular growth had extended into or through the lymphatics before any treatment was instituted; it was no longer a local process. When it comes to the study of serial biopsies of patients under treatment by radiation, and the drawing of conclusions attributing the response to radiobiologic reactions, I feel that a tumor pathologist should take over on the discussion, rather than to have the humble opinion of a cancer clinician. Regard for the high caliber of Dr. Wood's work forces me to say that my comment is not to be interpreted as criticism. It becomes a matter of assessing the cause or influence chiefly responsible for bringing about the changes noted histologically. In this country it has been for many years generally accepted that Broder's classification of tumors, based largely on their degree of differentiation, has served as a fairly accurate guide to the anticipated response to a given unit of radiation. I wonder whether Dr. Wood's interpretations are an elaboration and an effort at refinement of that classification as therapy is progressing, and yet I am not quite able to interpret it as such. We have for long known that many clinical factors influence the response in seemingly identical cases to treatment by irradiation. I might refer to just two, that is, secondary anemia and local sepsis. We are all familiar with the improved response to irradiation when these conditions are corrected. They are

Fig. 13.—Precancerous stretch of epithelium after administration of 1,000 r.

cated by an increase in differentiating cells, yet the prognosis is unfavorable if in later biopsies precancerous lesions persist. This persistence of precancerous lesions can be recognized only histologically, and months or years may elapse before frank malignancy supervenes and produces clinical symptoms. About

Fig. 14.—Precancerous stretch of epithelium after administration of 2,000 r.

one third of the failures in treatment in our series of carcinoma of the mouth and throat was due to the existence of precancerous lesions. It is interesting that the clinical history of such patients showed decided difference in the incidence and duration of "temporary healing," as compared with that of patients in whom frankly malignant tissue persisted in spite of treatment—80 per cent of patients with precancerous lesions enjoyed a period of complete freedom from symptoms.

controllable today, within reasonable limits and without undue effort, through the use of antianemic drugs and transfusions and by the antibiotics and local hygiene. I would like to suggest that a study such as Dr. Wood has so painstakingly done would be more convincing if all the cases, in addition to similar histologic standards and anatomic locations, be brought to a minimum clinical acceptance standard as well, before institution of the study and treatment. If all patients were selected within a middle life age level, with serious chronic diseases eliminated, with the blood picture brought up to a minimum standard and local and general sepsis eliminated actively by adequate local measures, plus the vigorous use of such antibiotics as penicillin and sulfonamide drugs, if necessary, the changes then found in serial biopsies would be more impressive and less liable to controversial interpretation.

DR. CHARLES L. MARTIN, Dallas, Texas: I, too, wish to express my appreciation to Dr. Wood for her excellent presentation. I am not capable of discussing much of her paper, but am certain that American radiotherapists will be interested in the material presented. Most of us agree that clinical results are not dependent on wavelength and that histologically similar tumors may behave differently when subjected to identical doses of radiation. However, a rather extensive experience with the radiologic treatment of metastatic cervical lymph nodes has led me to believe that the dose needed to eradicate squamous cell carcinoma in nodes is definitely larger than the dose needed for a primary lesion. It is my impression that most of the radiologists in this country are of the same opinion. Perhaps Dr. Wood will be good enough to give us some of her clinical data indicating that the radiosensitivity of cancer cells in the two locations is identical. The second portion of her paper, dealing with tumor cell counts as indicators of biologic effect, is a step in the right direction. Certainly, the time has come for us to develop some method of measuring biologic effect rather than ionization in terms of roentgens. In my opinion, the curability of cancer depends for the most part on the size of the total effective dose—and I wish to underline “effective”—regardless of how sensitive the cells may be to 1,000 or 2,000 gamma roentgens. In fact, my own best end results are obtained with tumors having the lowest radiosensitivity as we measure it in this country. Dr. Wood tells me that her total tumor dose amounts to about 6,000 gamma roentgens given in a period of about forty days. The effective dose with such factors is much smaller than that produced by 6,000 to 12,000 gamma roentgens given in seven days with low intensity radium needles with the technic favored by Sir Stanford Cade and myself. The larger doses should yield a higher percentage of cures. If this be true, her estimation of curability based on the cell response to only 1,000 to 2,000 gamma roentgens would not be applicable to technics such as ours. The work which she has presented is interesting, but I must admit a lack of enthusiasm for prognostic tests based on the administration of small amounts of radiation in short periods.

DR. B. W. WINDEYER, London, England: I was interested in the remarks made by Dr. Quick and Dr. Martin on radiosensitivity and differentiation. Dr. Quick said that it is generally accepted in this country that the Broders classification gave a rather good general index of radiosensitivity. I think that in Great Britain we have been increasingly disappointed with Broders' classification as an index of radiosensitivity. Personally, if I had an epithelioma of the lip, I would rather pray for one which was fairly well differentiated rather than an undifferentiated one, purely from the radiosensitivity point of view. I was also interested in Dr. Martin's view that the majority of his good end results were in cases in which there did not appear to be a great degree of radiosensitivity from a histologic point of view. I think that all these things link up somewhat with the report which Dr. Wood has given us, and I feel that the Broders' classification does not give a true view of radiosensitivity.

DR. CONSTANCE A. P. WOOD, London, England: Dr. Quick and Dr. Martin have referred to my comment on the response of glands to radiation. The accompanying figure shows a

graphic test for correlation between tumor regression time and glandular regression time. Each dot represents a patient; the glandular regression time is plotted along one axis and the tumor regression time along the other. It may be seen that there are about as many cases in which the glands responded more readily than the tumor as there are cases in which the tumor responded more readily than the glands, and there is a tendency for long glandular regression time to be associated with long tumor regression time, and vice versa. My co-workers and I conclude, therefore, that when doses of the same order are delivered to both the glandular region and the primary tumor the glands offer no greater resistance to radiation than does the primary growth. This conclusion is supported by a study we made of the spread of cancer at the time of death in about 400 patients with oral cancer, who died with cancer present. We found that the majority of patients who had no glands present when treated died without cancer in the glands, while those who had glands present at the time of treatment had cancer in both primary site and

Fig. 15.—Graphic test for correlation between tumor regression time (shown in the horizontal row of figures at the bottom, in days) and glandular recession time (shown in the vertical column of figures at the left, in days).

glands at the time of death. These observations do not support the generally accepted view that cancer in secondary glands yields less readily to radiation than does the primary growth. I agree with Dr. Quick that the more anaplastic types of growth are the most radiosensitive. It is important, however, to distinguish between radiosensitivity and radiocurability. We have found that the more highly differentiated types of squamous epithelioma give better end clinical results to radiation, though their initial response is not so rapid as in the anaplastic types. A higher proportion of patients with the anaplastic types had glands present at the beginning of treatment, and this type gave poor end results in both primary site and glands. The better results universally obtained in the treatment of cutaneous and lip cancer than, for instance, in oral cancer, must be attributed not to any refinements in radiologic technic but to the greater incidence of differentiated tumors in the skin. The method I have described of using cell counts is just one way of attempting to determine what biologic factors influence the response of cancer to radiation. A biopsy gives only a static

picture of what is happening in the tumor. With the advent of radioactive isotopes, we have weapons which make a more dynamic picture possible; and considerable progress has already been made along these lines by work with isotopes in the United States. I think that a better understanding of the action of radiation on the living cell offers the greatest possibility of any improvement in the radiation treatment of malignant disease.

THE DOCTOR AND THE NEW INTERNATIONAL LIST OF DISEASES AND CAUSES OF DEATH

HALBERT L. DUNN, M.D.
Washington, D. C.

The First World Health Assembly, on recommendation of the International Conference, prescribed on July 24, 1948, the use of the International Statistical Classification of Diseases, Injuries, and Causes of Death by its member nations. Thus, the first international morbidity-mortality code came into being. This fact is of significance to the medical profession, particularly those interested in comparability and uniformity of useful morbidity statistics produced by hospitals, clinics and medical insurance plans. Also of significance is the international adoption of a uniform medical certificate of causes of death on which will be based a new procedure for selecting the cause of death to be tabulated. In this new procedure, the physician plays the determining role by indicating the underlying cause to be tabulated.

Every ten years, it has been an international tradition to revise and modernize the international list of causes of death. In accordance with this tradition, an international conference was convened in Paris by the French Government from April 26 to 30, 1948. Delegates from 29 countries were present: Belgium, Bulgaria, Canada, Chile, Cuba, Czechoslovakia, Denmark, Ecuador, Ethiopia, France, Greece, Guatemala, Hungary, Iceland, India, Ireland, Italy, Luxemburg, Mexico, Netherlands, Norway, Poland, Portugal, Siam, Sweden, Switzerland, United Kingdom, United States of America and Venezuela.

The planning for the conference was carried out jointly by the health statisticians of the French Government and the Interim Commission of the World Health Organization. The latter had appointed an expert committee to carry out the preparatory work under the terms of the arrangement of July 1946, concluded by the governments represented at the International Health Conference. A truly epochal advance in the field of disease classification was made at this Sixth Decennial Conference for the Revision of the International List. For the first time, there was established a combined statistical classification for both sickness and causes of death. Previously, only mortality data had been coded according to an internationally accepted statistical classification. Now it will be possible to classify and tabulate both illness and cause of death by the use of the same code, thus making possible comparable morbidity statistics among hospitals, among clinics, among health departments of states and among the health agencies of the nations.

Sweeping changes were incorporated in the new international list. However, most of these changes

were made within the general structure of the previous international list of causes of death. The list was expanded considerably, from 450 to 610 categories for diseases and morbid conditions, with an additional 153 categories for the classification of external causes of injuries and 180 for the characterization of injuries in accordance with the nature of the injury. The injury classifications are supplements to the disease code, and either or both of these two supplemental classifications can be used, the first being particularly adapted for mortality coding and the latter for morbidity purposes.

The revised international list of diseases and causes of death consists of a list of three digit categories with a special fourth digit subdivision. The fourth digit subdivisions will be particularly useful for hospitals, clinics and specialized medical services. In contrast to the previous international code for mortality, the proposed classification is well adapted to mechanical tabulating equipment.

It should be mentioned here that the International Statistical Classification of Diseases, Injuries and Causes of Death is not intended to replace the Standard Nomenclature of Diseases and Standard Nomenclature of Operations, which is now being widely used in the United States. The function of a statistical classification is to provide quantitative data on groups of cases of allied diseases or conditions. On the other hand, a medical nomenclature is basically a list or catalog of approved terms for describing and recording clinical and pathologic observations which has important uses in the study of disease.

Manual of the International Statistical Classification of Diseases, Injuries, and Causes of Death.—A manual of the International Statistical Classification of Diseases, Injuries, and Causes of Death will be published by the World Health Organization in an English, a French and a Spanish edition. There will not be a United States' edition of the list as has been true in previous decennial revisions. All of the English-speaking nations have agreed to purchase their copies of the manual from the World Health Organization in the interest of greater international comparability in classification. The World Health Organization plans to publish this work in two volumes; the first, about 375 pages in length, consisting of the introduction, list of categories, tabular list of inclusion terms, rules for medical certification and classification of the joint causes of death, and certain selected lists for special tabulation purposes. Of particular interest to hospitals are the special supplemental sections on special admissions without illness, and provisions for the count of various types of deliveries. For statistical purposes, the World Health Assembly has recommended, as an interim measure, the inclusion as liveborn infants all infants who after complete separation from the mother show any signs of life. The second volume, approximately 520 pages in length, will contain an alphabetic index. Volume 1 has been published and it is expected that volume 2 will be available for distribution about July 1, 1949.

Other innovations were made at the Paris conference. One which is of particular interest and importance to physicians is the introduction of an international form for the recording of the causes of death in the medical certification of death. The method by which the questions are asked on the medical certificate will be uniform on death certificates throughout the world. This suggested form of medical certification, which is

basically the same as that used in the United States for the past ten years, places on physicians the responsibility for indicating the underlying cause of death, namely, the disease or injury which initiated the sickness or morbid condition leading to death (fig. 1).

Another innovation which is a radical departure from the previous procedure in the United States involves the scrapping of the Manual of Joint Causes of Death for selecting the primary cause of death when several causes are given jointly on the death certificate. Previously, these rules have been applied by code clerks in the processing of mortality statistics. Now, however, the physician's judgment as indicated by the order of the diseases placed on the medical certificate form will be used generally for determining the underlying cause of death. For many years, physicians in this country have wanted to bring about this change. Now that the change is being made, it will be necessary for the members of the profession to strive to secure a better understanding of the medical cer-

lying cause without recourse to any arbitrary joint cause priority system, if the statement of the causes of death is not inconsistent within itself. A few simple rules have been retained to apply to those cases where the entries made by the physicians are obviously given in the wrong order. These rules have been recommended by the World Health Organization and will apply uniformly in every country using the new international list.

IN CAUSE OF DEATH		MEDICAL CERTIFICATION		INTERVAL BETWEEN ONSET AND DEATH	
1. Disease or condition directly leading to death (a)		Pulmonary edema		1 day	
2. Antecedent causes		11. Other significant conditions		21. Autopsy	
3. Date of operation		12. Major findings of operation		22. Date signed	
21a. Accident		21b. Place of injury		21c. City, town, or township	
21d. Time of injury		21e. Injury occurred		21f. How did injury occur?	
22. I hereby certify that I attended the deceased from 19 to 19, that I last saw the deceased alive on 19, and that death occurred at 19, from the causes and on the date stated above.		23. Signature		24. Address	

Fig. 2.—Sample data.

The following example shows how variations in reporting of causes of death may affect the selection of the cause of death to be tabulated, and how the new coding procedure differs from the old joint cause priority system.

On Jan. 26, 1948, a 54 year old woman was admitted to the hospital with coronary sclerosis and was discharged on February 5 as improved. This woman had been receiving treatment for syphilitic aortitis since January 1938. On June 9, 1948, she was readmitted with myocardial infarction. On June 16 pulmonary edema developed, resulting in death on June 17.

If, in the physician's opinion, the pulmonary edema developed from the syphilitic aortitis, the medical certification of death should be made out as in figure 2. On the other hand, if the pulmonary edema was the consequence of myocardial infarction, the cause of death should be reported as in figure 3.

Under the old joint cause rules, both certificates would have been assigned to syphilitic aortitis. However, under the new system the coder accepts the doctor's statement of the underlying cause unless it is inconsistent within itself. Therefore, since the cause leading directly to death, pulmonary edema, could have been the

IN CAUSE OF DEATH		MEDICAL CERTIFICATION		INTERVAL BETWEEN ONSET AND DEATH

Fig. 3.—Sample data.

consequence of the train of events shown in part 1 of either certificate, the coder would make the assignment in accordance with the doctor's statement. The underlying cause of death shown in figure 2 would be syphilitic aortitis, and in illustration 3, heart disease involving coronary arteries. Thus, it is seen how important it is for the attending physician who knows most about the facts of the death to fill in the certificate to show the proper relation of the conditions involved in the death.

tification in order to secure more adequate medical information on death. Ultimately, the success of this new type of certificate will depend on the willingness of the attending physician to fill in correctly the information on death certificates.

In this country, the international form of medical certification has been incorporated into the 1949 revised standard death certificate. Without exception, state health departments have agreed to incorporate the international wording into the state death certificate forms. Most physicians are familiar with the change in wording since all the county medical societies were consulted by the National Office of Vital Statistics of the Public Health Service in the planning of the revision of the death certificate. The medical certification form does not differ radically from the one which has been in use over the last ten years. It is anticipated that the inclusion of explicit directions on the face of the form will aid physicians in recording a more complete and more accurate response.

The statistical clerk who receives the death certificate must accept the physician's judgment as to the under-

In agreeing on the new list and classification procedure, the international revision conference also recommended that, besides the usual primary cause tabulations, each nation publish annually a multiple cause tabulation designed to show the force of mortality for combinations of causes. To prepare such a tabulation, it will be necessary to code both the underlying and contributing causes for each death certificate filed. Unless the physician does his part of the job, the final statistical picture of health conditions in this country will not be complete and may even be misleading.

The new international list, certificate and coding procedure went into effect on Jan. 1, 1949. Many statistical offices will also use the old codes during 1949 so as to smooth the transition period and determine the degree of comparability between the death statistics of the 1940's and the 1950's. Of course, some comparability will be lost, but the change to a sounder medical basis of classification will be worth that sacrifice.

For many years, the comparability of causes of death in different localities of the United States and, with some reservations, international comparisons has been accepted. But, in the past, data on illnesses from two different hospitals even within the same state had to be qualified with explanations of whether they were using the Massachusetts General Classification, the United States Public Health Service Classification or some one of a dozen other classifications. Beginning Jan. 1, 1949 all hospitals availing themselves of the new manual will be able to compare their illness statistics. The Medical Research Division of the Veterans Administration is already classifying discharges from all Veterans Administration hospitals by the new morbidity-mortality code. Since the death certificates are classified in the same groups, the possibilities, which the Veterans Administration hopes to see materialize, of amassing data on relationships among the onset of a disease, its duration, the chances of survival, the frequency of complications and the relative value of different medical treatments, all seem to be closer to realization.

It is expected that the private and proprietary hospitals will also benefit by the use of the new international statistical code. These organizations have long expressed a need and a desire for a uniform morbidity classification for statistical purposes. The increasing number and varieties of public and private medical care programs, health and accident insurance plans will find the new statistical list designed to meet their needs. It will enable them to pool their experience statistically to arrive at better measures of morbidity risks.

The needs of national and international health programs can be met only through accurate and consistent mass statistical data. Just as public health thinking has progressed from saving lives to preventing disease, so the International Statistical Classification of Causes of Diseases, Injuries, and Deaths has kept step by making possible improved statistical studies of morbidity along with mortality.

American Legion Endowment Fund.—The American Legion raised a \$5,000,000 endowment fund in 1925, now increased to \$7,000,000, the income from which supports its National Child Welfare and Rehabilitation Services. The American Legion has expended since 1925 nearly \$70,000,000 in financial aid to needy children and veterans, most of the money going for medical treatment, food and clothing.—American Legion News Service, No. 140.

EFFECT OF URECHOLINE® ON THE STOMACH, INTESTINE AND URINARY BLADDER

I. F. STEIN JR., M.D.

and

KARL A. MEYER, M.D.
Chicago

Recent interest has been aroused in the drug urecholine®¹ (urethane of beta methylcholine chloride) by the demonstration of the stimulatory action of this drug on gastric motility following complete vagotomy. This action was first reported by Machella² and confirmed by Grimson,³ Stein,⁴ Smith⁵ and Dragstedt.⁶ Starr and Ferguson⁷ have reviewed the early literature and have demonstrated the value of urecholine® in post-operative urinary retention. The stimulatory effect of urecholine® on intestinal motility was reported by Youmans⁸ and has been further studied experimentally by Postlethwait.⁹

METHOD

The effect of urecholine® on the stomach was studied by means of kymographic tracing of gastric motility as well as clinical observations. A detailed report of the gastric motility studies was previously published.¹⁰

The effect of urecholine® on intestinal motility was studied by clinical observation of patients with adynamic ileus. The effect of urecholine® on the urinary bladder was studied both by manometric determinations of intravesical pressure and by clinical observation.

RESULTS

The results are summarized in the table.

Effect on the Stomach.—The motility response of the stomach to urecholine® was studied by us in 12 instances after complete vagotomy by placing a balloon in the stomach and recording on a kymograph. In each of 3 patients, 5.0 mg. of urecholine® given subcutaneously produced a decided increase in gastric tone and motility in five to ten minutes (fig. 1). When 10 mg. of the drug was given orally, in eight trials, there was usually a moderate to pronounced increase in the gastric motility in thirty minutes to one and one-half hours, lasting thirty minutes to three or more hours. Administration of 10 mg. of urecholine® sublingually produced a slight increase in gastric motility in 1 instance, whereas 25 mg. sublingually produced satisfactory stimulation. Clinical observations were made

From the Hektoen Institute for Medical Research of the Cook County Hospital and from the Departments of Surgery of the Cook County Hospital and Northwestern University Medical School.

of an additional 10 patients who had symptoms of gastric retention following complete vagotomy. The usual dose was 20 to 30 mg. three times a day before meals. The results were satisfactory in all cases. One patient required intermittent therapy for as long as five months.

Urecholine® was used in 5 patients in whom symptoms of poor gastric emptying or gastric retention followed gastric resection without vagotomy. The drug was given orally in doses of 10 to 20 mg. ten to twenty days following operation. In 4 cases the results were

* This case is also included under "oral."

† This case is also included under "subcutaneous."

excellent after the drug was given one to three times. In 1 case, repeated administration of the drug both orally and subcutaneously failed to produce gastric emptying. At reoperation, a kink was found obstructing the gastrojejunal anastomosis.

Symptoms of dizziness, warmth and epigastric fullness without vomiting were present in 2 of these patients after the ingestion of small amounts of food. These symptoms were completely relieved by the single or repeated administration of 10 to 20 mg. of urecholine® by mouth. It appears that small oral or sublingual doses of urecholine® may be of benefit in the treatment of the so-called postgastrectomy syndrome, or dumping stomach.

Effect on the Intestine.—Urecholine® was used on 20 cases of adynamic ileus. In 13 instances the patients passed gas and often feces in from ten minutes to two hours after the drug was given. The patients with more severe disease were given an initial dose of 5.0 mg. of urecholine® subcutaneously, followed in three hours by another injection or by 25 to 30 mg. orally or sublingually. The drug was repeated four times a day when necessary. Mild postoperative abdominal distention was usually relieved by the oral administration of 20 to 30 mg. of urecholine®. The response was variable in 5 patients, and gradual improvement was noted over a period of two or three days. Urecholine® failed to relieve the abdominal distention in 2 cases, in both of which only a single dose of the drug was given.

The use of urecholine® in adynamic ileus is illustrated in 2 cases:

CASE 1 (R. T.).—The patient was a 60 year old Negro who entered the hospital with a two day history of cough, pain in the chest, chills and fever. Physical examination revealed an acutely ill man with a temperature of 103 F., pulse rate of 120 and a respiratory rate of 40. Dulness, decreased breath sounds and rales were present over the left side of the chest. The results of the remainder of the physical examination were essentially normal. A diagnosis of left lobar pneumonia was made and confirmed by roentgenogram. A dose of 30,000 units of crystalline penicillin was given every three hours. The following day the condition of the patient was unchanged

Fig. 1.—Effect of urecholine® on gastric motility.

except for the appearance of moderate distention of the abdomen. On the third hospital day, the abdominal distention became pronounced and the patient vomited. Gastric decompression was started, and intravenous fluids were given. A roentgenogram of the abdomen revealed gas-filled loops of both large and small intestine. On the fourth hospital day the temperature was 101 F., the pulse rate was 100 and the respiratory rate was 30. The abdomen was decidedly distended. The patient had passed no gas, and no relief was obtained with enemas or a rectal tube. On the fifth hospital day the condition was essentially unchanged. The patient had not passed flatus or stool in five days. An enema again failed to relieve the distention. The patient was then given 5.0 mg. of urecholine® subcutaneously. In ten minutes there was a copious passage of flatus, followed in one hour by a bowel movement. The Levine tube was removed, and within twelve hours the abdominal distention was gone and oral feedings started. The patient made an uneventful recovery.

CASE 2 (W. T.).—The patient was a 65 year old Negro who entered the hospital with a five day history of tenderness in the right inguinal region, cramping abdominal pain and vomiting. Physical examination revealed an acutely ill man with an extremely tender, incarcerated inguinal hernia. The patient was prepared for operation with Levine suction and fluids, including blood, given intravenously. At operation a gangrenous loop of small bowel was found in the hernial sac. This was resected and an end to end anastomosis performed. Postoperatively the patient was treated with penicillin, intra-

venous fluids and Levine suction. The patient was afebrile by the third postoperative day, but the abdomen remained decidedly distended. On the seventh postoperative day the patient still was decidedly distended. There had been no passage of gas or stool since five days before operation, or a total of twelve days. The abdomen was not tender, and occasional low pitched bowel sounds were present. It was apparent that the general condition of the patient was rapidly failing because of the severe adynamic ileus. Although urecholine® may be contraindicated after a recent intestinal anastomosis, the patient was given 5.0 mg. of urecholine® subcutaneously. Ten minutes later he passed a large amount of gas by rectum and shortly thereafter had a copious bowel movement. Within an hour the abdominal distention was almost completely relieved. The Levine tube was removed, and oral feedings were started. The patient subsequently made an uneventful recovery without further medication.

These 2 patients with adynamic ileus showed a prompt response to treatment with urecholine®. In the majority of cases the response was less dramatic and took place over a period of several hours.

A patient with a large ventral hernia was given 5.0 mg. of urecholine® subcutaneously in order that we

Fig. 2.—Effect of urecholine® on intravesical pressure. The vertical values at the left show bladder pressure in inches of water; the horizontal values show time in minutes.

might observe directly the effect of the drug on the motility of the small bowel. In ten minutes there was a decided increase in the bowel sounds and in both palpable and visible peristalsis. Three children and 1 adult suffering from megacolon received urecholine® orally for varying periods. In 1 case there was clinical improvement.

Effect on the Bladder.—An injection of 5.0 mg. of urecholine® was given subcutaneously to 18 patients with postoperative urinary retention. Fifteen of these patients voided in three to ten minutes following the injection. Catheterization was performed if the patient did not void in fifteen minutes, as was the case in 3 of the patients.

Urecholine® was used for urinary retention in 2 patients with transverse myelitis. In 1 patient (case 3) the result was entirely satisfactory. The other patient was extremely ill, and no beneficial effect was noted.

Two patients with urinary retention due to spinal cord injury and resultant paraplegia were treated with urecholine®. The evacuation of the bladder in 1 patient (case 4) was completely controlled by urecholine®. The

second patient (case 5) was relieved of urinary retention by the use of the drug.

The effect of urecholine® on the intravesical pressure was studied in 4 patients suffering from urinary retention (fig. 2). In all 4 patients there was a prompt increase in the intravesical pressure which reached a maximum in three to ten minutes. Ten minutes after the drug was given, the catheter, through which manometric readings were taken, was removed. In each case, the patient voided spontaneously within one minute. A brief summary of these 4 cases follows.

CASE 3 (A.R.).—The patient was a 40 year old white woman who had entered the hospital fourteen weeks previously with paralysis of both legs. A diagnosis of transverse myelitis was made, and the patient gradually regained the use of her legs. She was unable to urinate, however, and a retention catheter had been used most of the time. On four occasions the retention catheter was removed, but the patient was unable to void and intermittent catheterization was done. On three different occasions the patient was given 0.25 mg. of neostigmine every three hours for four doses, with no effect. After fourteen weeks of inability to urinate, urecholine® was tried. Three hundred cubic centimeters of sterile water was injected into the bladder, and the indwelling catheter was connected to a water manometer for the measurement of intravesical pressure. The basal pressure stabilized in less than five minutes at 4.5 inches (11 cm.) of water. Then 5.0 mg. of urecholine® was given subcutaneously. In two minutes the pressure began to rise, reaching a maximum of 23½ inches (60 cm.) of water in ten minutes. The catheter was then removed and the patient voided spontaneously. Five hours later she was given another 5.0 mg. injection of urecholine®, after which she urinated in five minutes. At this time she had 200 cc. of residual urine. The following day oral medication was started, 25 mg. of the drug three times a day. She urinated spontaneously, and the residual urine gradually decreased to 30 cc. at the end of two weeks, at which time urecholine® therapy was stopped. At the time of reporting she had had no further difficulty.

CASE 4 (J.H.).—The patient was a 48 year old Negro who had been shot in the abdomen. On entering the hospital shortly after being shot, he had signs of peritonitis as well as flaccid paralysis of both legs. At emergency operation, two perforations of the stomach and three of the jejunum were repaired. The transverse colon, containing two additional perforations, was exteriorized. An indwelling catheter was placed in the bladder. The patient made an uneventful recovery from operation, but the paraplegia was unaffected. Two weeks after operation, when ample time had elapsed for complete healing of the sutured stomach and jejunum, manometric readings were taken of bladder pressure. Three hundred cubic centimeters of sterile water were instilled into the bladder. After the pressure was stabilized at 5 inches (13 cm.) of water, 5.0 mg. of urecholine® was given subcutaneously. The pressure rose steadily, reaching a peak of 25 inches (64 cm.) of water after ten minutes. The catheter was then removed, and the patient voided. The patient was then given 25 mg. of urecholine® orally three times a day, as well as three daily injections of 5.0 mg. He voided after each injection, and after two days there was only 30 cc. of residual urine. After one week, the treatment was stopped. The urine then began to overflow, with 1,000 to 1,400 cc. in the bladder. At the time of writing, he was receiving frequent injections of urecholine® again and voiding after each injection.

CASE 5 (B.S.).—The patient was a 30 year old white man who had a broken back six years prior to examination, with resulting paraplegia. Three weeks prior to examination he had had a cordotomy for intractable pain in his legs. He had been unable to void, and an indwelling catheter was in place. One hundred and fifty cubic centimeters of potassium permanganate solution (1 to 5,000) was instilled into the bladder. After the basal pressure was stabilized at 17 inches (43 cm.) 5.0 mg. of urecholine® were given subcutaneously, following which the

intravesical pressure went up to 43 inches (109 cm.) at the end of ten minutes. The catheter was removed, and the patient voided. At the time of reporting, his bladder was overflowing with a small capacity and will probably require some form of tidal irrigation.

CASE 6 (D. H.).—The patient was a 36 year old white woman who had a cystocele and rectocele repaired with spinal anesthesia. An indwelling catheter was kept in the bladder for four days after operation. On removal of the catheter the patient could not void and required additional catheterizations for ten days. During this time the patient was given neostigmine (0.5 mg. every four hours for four doses) on three different occasions without effect. Urethral sounds were passed, and there was no stricture. On the fourteenth post-operative day manometric readings were taken. Three hundred and fifty cubic centimeters of sterile water was injected into the bladder, and the pressure was stabilized at 5.5 inches (14 cm.) of water. Three minutes after 5.0 mg. of urecholine® had been given subcutaneously, the intravesical pressure had risen to 31 inches (79 cm.). After ten minutes the pressure was 26 inches (66 cm.) of water. The catheter was then removed, and the patient voided 250 cc. Six hours later she was given another 5.0 mg. injection, five minutes following which she voided 350 cc. The following morning she voided 600 cc. spontaneously, with no residual urine, and remained asymptomatic.

Effect on the Heart.—A subcutaneous injection of 5.0 mg. of urecholine® had no effect in 2 cases of paroxysmal auricular tachycardia.

COMMENT

Urecholine® is a parasympathomimetic drug which acts on the stomach, intestine and bladder in the presence or absence of the preganglionic parasympathetic innervation. The effect is similar to that of doryl® (carbamylocholine chloride), although probably less toxic because of a weaker nicotine-like action.⁷ Urecholine® appears to have little if any action on the heart. In several cases electrocardiograms were taken while the drug was being given, with no noticeable effect. There has been no effect noted on the blood pressure or the pulse rate.

Dosage and Method of Administration.—The dosage and method of administration of urecholine® must be selected in each case. Intravenous injection was not attempted. Intramuscular injection was given in 10 instances, and, since the results were similar to those obtained after subcutaneous injection, these cases have been included in the text and in the table under the heading "subcutaneous." A dose of 5.0 mg. of urecholine® given subcutaneously produces a rapid but transitory increase in the tone and motility of the stomach, intestine and urinary bladder. This amount has been given as often as every four hours for four doses. A dose of 10.0 mg. of the drug given orally usually causes gradual increase of gastric and intestinal motility. The oral administration of 30 mg. of urecholine® usually causes a decided increase in the motility of the stomach and intestine as well as an increase in the tone of the urinary bladder. This dose has been given as often as three times a day. Sublingual administration of 10 to 30 mg. of urecholine® may produce mild contractions of the stomach or intestine.

Toxic Symptoms.—The toxic symptoms or side effects have been few in number and in no case serious. A feeling of warmth, flushing and sweating occur in about one quarter of the cases after subcutaneous injection of the drug. Mild abdominal cramps may occur after the subcutaneous or oral use of the drug. There

is occasional salivation. In no case was it necessary to give atropine to counteract the effect of urecholine®.

Contraindications.—The contraindications to the use of urecholine® are based on theoretical considerations. Urecholine® may cause a decided increase in gastric and intestinal peristalsis and should not be used after a gastrointestinal anastomosis until healing has taken place. The drug should not be used in the presence of peritonitis or mechanical intestinal obstruction. Urecholine® may cause contraction of the pregnant uterus, and, until this action has been studied, the drug should not be used during pregnancy. Urecholine® should not be given to an asthmatic patient, for it may precipitate an attack.

SUMMARY AND CONCLUSIONS

Urecholine® (urethane of beta methylcholine chloride) is a potent parasympathomimetic drug with relatively low toxicity and no serious side effect. It causes an increase in gastric motility in both the normally innervated and in the vagotomized stomach. It causes an increase in intestinal motility and is of definite value in the treatment of adynamic ileus. Urecholine® causes contraction of the normally innervated bladder as well as the cord bladder and is of considerable therapeutic value in the treatment of post-operative urinary retention. The value of urecholine in the treatment of cord bladder is yet to be determined.

ROENTGENTHERAPY IN CANCER OF THE HYPOPHARYNX

FRANCOIS BACLESSE, M.D.
Paris, France

The prognosis for cancer of the hypopharynx is poor because tumors occurring in this site are usually of an ulcerating and destructive nature. Complications, such as infection, involvement of the cartilage and sometimes considerable extension to the surrounding structures, make these lesions difficult to cure.

ANATOMIC CLASSIFICATION

The upper or membranous portion of the hypopharynx includes the whole aryepiglottic fold and the thyrohyoid membrane. The upper limit is the pharyngoepiglottic fold and the lower limit, approximately, the mucous fold of the superior laryngeal nerve. Radiographically, this part is projected between the hyoid bone and the superior border of the thyroid cartilage.

The lower or osteocartilagenous portion of the hypopharynx is deep, narrow and hidden. It is limited laterally by the thyroid lamina and medially by the arytenoid and the cricoid cartilages covered by muscles and fascia.

The distinction between the two parts is of particular significance when one considers the prognosis. Among patients at the Curie Foundation, those surviving five years, for the most part, are patients in whom the cancers originated and developed in the upper part of the hypopharynx. With two exceptions, lesions originating in the lower part have not been cured.

These results may be explained partly by the fact that carcinomas of the upper part are often fungating and bulky while those of the lower part are more often

From the Curie Foundation, Paris.
Read before the Section on Radiology at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 24, 1948.

ulcerating and destructive. The latter rapidly infiltrate the walls, the arytenoid and cricoid cartilages, their muscles and the thyroid lamina. Involvement of these structures creates biologic conditions less favorable than those produced by lesions of the aryepiglottic fold, away from the cartilages and articulations.

Therefore, cancers of the two areas may be described as: (1) cancers of the upper part, including epitheliomas of the aryepiglottic fold and the anterosuperior part of the pharyngolaryngeal fold, which can be cured when they are proliferative, and (2) cancers of the lower part, including those deep in the pyriform sinus, lesions involving the posteropharyngeal area of the arytenoid and the cricoid, and the mouth of the esophagus, or the posterior wall of the hypopharynx. They are much more difficult to cure and practically incurable when they are ulcerating (fig. 1).

In early cases the diagnosis is easy but in advanced cases, laryngoscopic examination is the only way to determine the origin of the disease. This examination should be made during and at the end of treatment,

Fig. 1.—Prognostically favorable (upper row) and unfavorable (lower row) types of hypopharyngeal cancer.

after partial or total regression of the tumor. The observations should be supplemented by radiographic examination.

Anteroposterior and lateral view roentgenograms of the neck to show the pharynx may reveal three radiographic signs which point to the diagnosis of tumor of the upper part of the hypopharynx: 1. The space between the hyoid bone and the superior border of the thyroid cartilage, ordinarily clear, shows a shadow of increased density due to tumor. 2. The superior thyroid horns are not pushed forward; they remain in contact with the cervical part of the spine. 3. The flexibility of the pharyngeal wall is preserved. In the Valsalva test, the thyroid and cricoid cartilages are pushed forward and the lumen of the hypopharynx above the level of the superior half of the cricoid becomes dilated.

The radiographic signs of cancer arising in the lower part of the hypopharynx are: 1. The posterior pharyngolaryngeal shadow is thickened in its superior arytenoid segment or in the inferior cricoid part, or in both. 2. The superior thyroid horns, and occasionally the cricoid, are pushed forward. 3. Flexibility of the

pharyngeal wall is observed to be decreased in the Valsalva test. However, some normal patients are unable to distend their hypopharynx with air.

The degree of flexibility is better demonstrated if the radiograph is taken immediately after oral administration of barium sulfate. The details of the lower part of the pharyngeal "funnel" are outlined by the opaque medium.

INCIDENCE OF CANCER OF UPPER AND LOWER PARTS OF THE HYPOPHARYNX

Clinical and radiographic studies of 240 patients treated during a ten year period yielded the following results:

Cancers of the upper part.....	70
Cancers of the lower part (of which 11 arose in the cricoid region)....	100
Cancers of the posterior part of the hypopharynx.....	52
Not classified because too extensive, treatment not completed, etc.....	18
Total.....	240

These figures indicate a greater incidence of lesions of the lower part of the hypopharynx ($100+52=152$).

FIVE YEAR SURVIVALS AND FOLLOW-UP

From 1921 to 1942, 425 patients were treated for cancer of the hypopharynx. Until 1937, most of the patients were treated by Dr. Coutard, or under his supervision. Of the 425 patients, 27 (6 per cent) were living and apparently healed after five years. Follow-up concerns only those patients who survived five years or more.

Of the 27 patients apparently cured five years after treatment, continued observation over a period of six to nineteen years showed:

- 3 patients lost to follow-up
- 6 patients died of intercurrent disease
- 1 patient died of late local recurrence
- 2 patients died of late distant metastasis (1 case of abdominal lymph nodes, 1 lungs and kidney metastases)
- 7 died from a second cancer

By second cancer is meant a carcinoma originating in another organ or, if in the initial area, clearly separated from the site of the first lesion. It is thus distinguished from the recurrence in situ. The 7 cases of second primary tumors include 2 cancers of the thoracic esophagus and 5 recurrences arising within the irradiated area but decidedly away from the first cancer. These sites are sufficiently interesting to warrant further discussion. They appeared between the sixth and tenth year, most of them occurring about the seventh year. It is interesting to note that 4 of the patients were among the group treated by Coutard in 1932 and 1933. The best results were obtained during those two years; of 8 patients treated, 4 were alive and apparently cured after five years. They later died from a second cancer. It may be pure coincidence; nevertheless, this percentage, even for a very low number, merits some consideration.

The doses given these patients were high (total skin dose distributed over two fields was 7,000 r, 7,500 r, 8,800 r and 9,100 r). On the other hand, these doses were given over a relatively short period, sixteen, twenty-eight, thirty-four and forty-five days. Moreover, treatment was delivered through large fields of 100 sq. cm. or more. All these patients except the one treated over the forty-five day period had severe reactions, i. e., cutaneous changes and muscular and deep tissue sclerosis. One patient required tracheotomy two months after the treatment, and it was necessary for him to retain his cannula permanently.

In contrast, the 7 surviving patients treated from 1937 to 1942 had no postradiation complications and,

so far, have shown no second cancer in the irradiated area. These patients received doses sometimes higher, but over a longer period (from sixty to seventy-four days) and through much smaller fields (10 to 50 sq. cm.). The two latter factors seem significant.

These observations are too few to draw any definite conclusions. However, it seems better to obtain local

TABLE 1.—Incidence of Lymph Node Involvement and Site of Origin of Cancer, 1936-1945 (10 Years)

Total.....	239	192	47

healing without damaging the surrounding tissues; for this reason the old method was discarded long ago. My co-workers and I now attempt to reduce cutaneous reactions by prolonging treatment time and by reducing the size of the fields while increasing the total dose.

LYMPH NODE METASTASES

The lymph node metastases deserve special consideration because of their frequent occurrence and the difficulty in curing them.

Table 1 shows the incidence of lymph nodes arising in the three areas, upper, lower and posterior part of the hypopharynx of 239 patients treated from 1936 to 1942.

It may be noted that the incidence of lymph node metastases is nearly the same for tumors of the upper and lower part of the hypopharynx but that they occur

TABLE 2.—Roentgentherapy and Course of 7 Apparently Cured Patients, 1937-1942

Case No.	Age, Yr.	Site of Tumor, Hypopharynx	Lymph Node Size	Approximate Tumor Dose, R	Treatment Period, Days	No. of Years Living current and Well	Died of Disease
1	80	Upper part	1.5 cm.	6,500	57	..	After 9 yr.
2	69	Upper part	3.5 by 3 cm.	(1)6,000	Treated 31 Interruption 51 Treated 17 (2)5,500 Recurrence 49	..	8
3	63	Upper part		5,200	73	9	
4	61	Upper part	3 by 2 cm.	6,900	74	8	
5	64	Upper part		6,800	57	7	
6	57	Upper part		7,400	69	7	
7	74	Lower part	6.5 by 5.5 cm.	6,200	64	6	

less frequently when the primary carcinoma arises on the posterior wall. Because the incidence of lymph node involvement for the upper and lower parts is the same, it seems that failure to cure lesions of the lower part is due not so much to metastasis as to the creation of the biologic conditions mentioned earlier. During the past few years, several pertinent observations have been made, though they are too recent to be included in our statistics. On the one hand we noted the frequent disappearance of the lymph nodes at the end of treatment, or sometimes later. On the other hand,

the primary tumor was not sterilized by the treatment. These two facts seem contradictory and warrant further study.

Of 186 cases of clinically metastatic lymph nodes treated from 1937 to 1945, 50 showed clinical disappearance of the lymph nodes for six months to one year or more. The patients died later of local recurrence. These unilateral or bilateral lymph nodes were classified as to whether they were smaller or larger than 3 cm. in diameter. Clinical disappearance of nodes when the cancer was localized was noted as follows: Of nodes smaller than 3 cm. in diameter, 1 disappeared of 7 treated; of 19 with a diameter larger than 3 cm., 6 disappeared; of 2 patients with bilateral involvement, 1 got well. When the cancer was extensive the corresponding proportions were 10 in 41; 22 in 87, and 10 in 30.

The percentage of clinical disappearance of the lymph nodes has increased during 1946 and 1947, and this is true for the oropharynx and nasopharynx as well as for the hypopharynx. In other words, in a great num-

Fig. 2.—Evolution of cutaneous reactions as modified by prolongation of the treatment period and reduction in size of the field.

ber of recent cases, lymph nodes, even rather large ones, seem more amenable to treatment, at least temporarily, than the primary tumor. Explanation may be found, at least in part, in some technical consideration.

TECHNIC

During the last ten years, technic in the radiotherapy department of the Curie Foundation has been directed in the following manner. Attempts are made to avoid exudative reactions. Mucous membrane reaction, when it is produced, should be mild, so that treatment may be continued. If more or less intense reaction is produced in spite of measures to prevent it, treatment is stopped temporarily to that area for the duration of this reaction. In the meantime, irradiation is continued to the lymph nodes through tangential fields which avoid the pharynx.

The total skin dose per field is increased considerably over the generally accepted limits. This increase is possible only when two conditions are observed: First, the size of the field must be reduced after a certain dose and the lymph nodes irradiated tangentially. Second, the fractionation must be prolonged beyond the

period of four to six weeks which is now used by most radiotherapists. The study of this fractionation has led to the following observations:

1. To avoid moist epithelitis, it is important to know the exact time when reaction will appear, for in the course of a continuously and rhythmically conducted treatment there is a precise time (within two or three days) when it will be produced. The first period, as is well known, occurs at the end of the fourth week. It is the classic epidermitis, described by Regaud, which Coutard produced systematically at the beginning of his clinical research. This is followed by other characteristic reactions at regular biweekly intervals. The second period occurs at the end of the sixth week (thirty-nine to forty-two days), the fourth at the end of the tenth week and the fifth at the end of the twelfth

fields, tangential fields for the lymph nodes. Thus the total skin dose reached at the end of twelve weeks coincides with the limit of tolerance of the tissues, about 7,000 or 8,000 r.

Coutard stated the belief that he had established a relation between the periodic mucosal reactions he observed and the curability of cancer. In my opinion, the critical periods of cutaneous reaction are important because they point a way to increase the total dose. By keeping the dose below a certain amount for each period, it is possible to continue treatment and the total dose may be considerably increased.

There are two main therapeutic problems: (1) the effect of irradiation on the cancer cells which sometimes demand considerable dosage and (2) the protection of the surrounding tissue which is achieved through

week. These periodic reactions become apparent only if irradiation is given daily or every other day, with reduced doses and rotating fields.

2. By avoidance of exudative epithelitis, treatment may continue without interruption until the next critical period, and so on during eight, ten and twelve weeks.

3. To avoid the exudative epithelitis at the known and expected times, it is important not to exceed a certain dose for each term of the fourth, sixth, eighth and tenth weeks. At the end of treatment, which may last from six to twelve weeks according to the individual case, the moist epithelitis may appear without inconvenience because the planned dose has been delivered. The higher this dose may be, the longer the period of fractionation.

4. It is possible to give twice as much dosage per field with minimal damage to the tissues by adhering to the rules, namely, small fields, reduction in size of field even toward the end of treatment, alternating

fractionation. Fractionation is probably less important in sterilization of the cancer cells, but its role in protecting normal tissues is much more important than is sometimes admitted.

According to this theory, there is no rigid routine in treating cancers in general, and this includes lesions of the pharynx. Selection of the most effective total dose with fractionation may be made from figure 2, and the choice is influenced by the clinical observations, i. e., site and extent of the lesion, presence or absence of lymph nodes and fast or slow regression of the lesion during treatment.

The application of this method of irradiation requires strict technic. It is made easier by the use of the light-directed and diaphragm-controlled beam. The diaphragm of the localizer consists of movable plates which permit great adaptability of the fields of the configuration of the area to be treated. Special localizer tubes can be adapted to the diaphragm which are

especially useful near the end of treatment when the size of the lymph nodes has been reduced. Centering over very small fields is done rapidly, accurately and easily. The localizer tube attached to the diaphragm has a movable glass surface which may be flat or oblique, according to the area to be irradiated. The small illuminated skin surface is well visualized through the glass, and the center of the skin field is easily recognized if marked with a skin pencil. I believe that the increased skin dose, made possible by this technic of small well centered fields, explains the disappearance of lymph nodes, even large ones, noted in the past few years.

On the other hand, sterilization of the primary tumor seems much more difficult. While failures are due partly to the anatomic and clinical conditions previously outlined, the difficulty in delivering sufficient irradiation to the remaining primary tumor through a very small field is also responsible. The radiotherapist must stress greater technical precision in centering over the site of origin of the cancer.

Table 2 shows the approximate tumor dose and the duration of treatment period for 7 patients treated from 1937 to 1942 and apparently healed five years or more. The site of origin in 6 of these was in the upper part and 1 in the lower part of the hypopharynx. Four patients had lymph nodes, one measuring 6.5 by 5.5 cm.

The tumor doses are high, varying from 5,200 to 7,400 r. Fractionation was from fifty-seven to seventy-four days except for 1 patient whose treatment was irregular because of war conditions. First, the tumor received approximately 6,000 r over a period of ninety-nine days in two series (treated thirty-one days, rest fifty-one days, treated seventeen days). After this there was a local recurrence which was again treated fourteen months later with a tumor dose of nearly 5,500 r over forty-nine days. The last course was given without interruption. The lymph nodes (3.5 by 3 cm.) and the hypopharyngeal lesion disappeared, and the patient was apparently well after eight years.

The postirradiation changes in all these patients have been minimal. The treatment was tolerated without incident, and this is remarkable because some of these patients were very old. Results here are different than the complications noted when the total dose was less and given through a larger field in a shorter period of time.

COMPARISON OF FIVE YEAR RESULTS IN ORO-PHARYNX AND NASOPHARYNX CARCINOMA

Tables 3 and 4 show the five year result in oropharynx and nasopharynx epitheliomas classified according to the extent of the lesions. Of 318 patients with carcinoma of the oropharynx, 25 were well after five years, and of 95 patients with epithelioma of the nasopharynx, 13 were living and well after five years. The prognosis seems slightly better for the vallecular and epiglottic lesions than for the other areas and, on the whole, the rate of cure for the nasopharyngeal carcinomas is a little better than for those of the oropharynx.

SUMMARY AND CONCLUSION

By studying each case clinically and radiographically to localize the site and origin of the cancer, by adhering to a dosage schedule pertaining to the time of appearance of biologic reaction and by further protracting the course of treatment, one may hope for a cure in more cases of carcinoma of the hypopharynx. The

ulcerating and destructive tumors will remain a difficult problem for some time. Technical improvements alone will not suffice, and radiologists, collaborating with biologists, should search for methods of increasing the sensitivity of these tumors.

ABSTRACT OF DISCUSSION

DR. JUAN A. DEL REGATO, Columbia, Mo.: We are honored to welcome Dr. Baclesse as the representative of the Radium Institute of the University of Paris. The clinical endeavors of the French school are widely appreciated by the pragmatic radiotherapist of this country. Dr. Baclesse has distinguished himself for his radiographic study of the pharynx and larynx and also for his work in the treatment of advanced carcinoma of the cervix. He now brings the results of roentgen therapy on a remarkably large series of cases that includes all of Coutard's material. These results, however poor, have not been obtained easily. Dr. Baclesse has noted the relatively better prognosis of carcinomas arising near or around the free border of the epiglottis. It is pertinent to emphasize that the lesser curability of the others is not due to difference in radiosensitivity but to their early invasion of vascular structures and laryngeal cartilages and to the extensive necrotic defects that result from their irradiation. The presence of a metastatic adenopathy is not a factor of incurability, since many of the patients that are cured presented metastasis when treated. These facts should help us to come to an agreement on the concept of radiosensitivity, a word so variedly interpreted and so widely misused, as different from radiocurability. From *stagier* at the Foundation Curie in the 1920's Baclesse has risen to become one of Europe's most distinguished therapeutic radiologists and to be recognized as Coutard's most brilliant pupil; we are pleased to congratulate him for his fine presentation, but we must congratulate ourselves also for the opportunity of listening to him.

DR. MAURICE LENZ, New York: According to Dr. Baclesse, prognosis in cancer of the hypopharynx is not good. It is especially bad when the origin of the growth is in the lower portions of this cavity. By prolonging roentgen therapy for cancer of the hypopharynx to ten or twelve weeks, Baclesse was able to administer larger tumor doses than given heretofore, without a corresponding increase in the radiation damage of the normal tissues included in the irradiated area. Increased protraction of the treatment period holds even more promise in irradiation of large volumes of the body and in those regions in which the normal tissues are especially radiosensitive. It has been used by Baclesse and others in roentgen therapy of cancer of the cervix, breast and other sites. For instance, the Standardization Committee of the American Radium Society (*Am. J. Roentgenol.* 38: 377, 1937) reported that proctitis complicating radiotherapy of cancer of the cervix in the experience of its members occurred chiefly when the time for the administration of intracavity radium treatment was forty hours or less and the roentgen therapy a correspondingly short period. My co-workers and I investigated this problem because of a number of intestinal complications caused by this technic at the Presbyterian Hospital, New York; these stopped occurring as soon as we increased the treatment period (*Am. J. Roentgenol.* 39: 871 [June] 1938). In cancer of the breast (*Acta Radiol.* 28: 583, 1947) we gave larger doses than were given previously by prolonging the treatment to three months. Regaud and Coutard were the first to stress the advantage of protraction, but neither carried it to the degree that Baclesse has. Baclesse has tried to avoid radio epithelitis and has now cured patients without producing the severe mucous membrane reaction. It is this lessening of damage to the normal structures without reducing the number of cures for which Baclesse deserves credit; I congratulate him.

DR. FRANCOIS BACLESSE, Paris, France: With this method, in ten weeks—and, even in the very extensive condition, in twelve weeks—the following facts are noted: First, in a certain number of cases, there was clinical disappearance of

the lymph nodes, even when enlarged. Second, the healing of the primary lesion is more difficult to obtain. For example, of 186 cases of lymph nodes treated from 1937 to 1945, a clinical disappearance of the lymph node was obtained for a duration of six months to one year and more in 50 of the patients, the patients dying later from a local recurrence. The percentage of the clinical disappearance of the lymph node has increased during 1946 and 1947, and this applies to the hypopharynx as well as to the oropharynx and the nasopharynx. In other words, presently, and in a great number of cases, it seems easier to make the lymph nodes—even rather large ones—disappear, at least temporarily, than the primary tumor. These facts can be explained, at least partly, by some technical and biologic considerations, such as a large dose, well centered, through small fields, at the end of the treatment and with fractionation over a long time—eight, ten and even twelve weeks.

THE CORNELL MEDICAL INDEX

An Adjunct to Medical Interview

KEEVE BRODMAN, M.D.
ALBERT J. ERDMANN Jr., M.D.
IRVING LORGE, Ph.D.
and
HAROLD G. WOLFF, M.D.
With the Technical Assistance of
TODD H. BROADBENT
New York

It has been the purpose of this investigation to develop a quick and reliable method of obtaining important facts about a patient's medical history without expenditure of the physician's time. The Cornell Medical Index, the method developed, is a form on which persons undergoing medical examination indicate their symptoms and other significant medical information before being interviewed. As will be shown, the Cornell Medical Index collects a large body of data similar to that recorded in comprehensive hospital medical histories, so that the physician has at hand, even before he interviews the patient, information on which to base tentative diagnostic and prognostic appraisals of the patient's total medical problem.

This communication describes the Cornell Medical Index and compares the data it collects with information recorded by examining physicians in the hospital histories of patients in the general medical department of a large teaching hospital.

DESCRIPTION OF THE CORNELL MEDICAL INDEX

The Cornell Medical Index (abbreviated C.M.I.) is a four page letter-sized sheet. Like the psychiatric forms of the Cornell Index,¹ the C.M.I. collects data by asking questions. The 195 questions on the

C.M.I. were chosen to correspond closely to those usually asked in a detailed and comprehensive medical interview, including many on the psychologic aspects of the patient's disorder. Questions are in informal language and worded to be understood by persons with a reading knowledge of simple English. Technical terms are avoided, but when their use is necessary an explanation is given. Thus, diabetes is explained as "sugar disease," urinate as "passing water" and varicose veins as "swollen veins." After each question a "Yes" and a "No" appear; the patient answers the question by circling one. In every instance, a "Yes" response indicates that the patient does have the symptoms about which he is being questioned.

In constructing the C.M.I., items were selected only after a pilot study of more than 1,000 subjects had shown that the items collected data accurately. The questions are of four kinds: those relating to bodily symptoms (for example, "Do you usually feel bloated after eating?"), those relating to past illnesses ("Has a doctor ever said you had kidney or bladder disease?"), those relating to family history ("Did anyone in your family ever have a nervous breakdown?") and those relating to behavior ("Do you often feel unhappy and depressed?").

The questions on the C.M.I. are arranged in sections headed by letters of the alphabet, questions in each section being related. A list of these sections, together with the number of questions in each, is given in table 1.

There are two forms of the C.M.I., one for men and the other for women. Both are identical except for six questions in the genitourinary section.

The C.M.I. is headed: Cornell Medical Index, Health Questionnaire. The term "Cornell Medical Index" distinguishes this from the psychiatric forms of the Cornell Index (the military Form S and the civilian Form N2). "Health Questionnaire" explains the nature of the form to the patient and has been shown by test to reduce the patient's suspicion about the purpose of the questions.

The C.M.I. is administered simply by handing the form to the patient and asking him to complete it. It can be administered to patients either individually or in groups, the additional equipment necessary being a pencil or pen and a table or board on which to rest the form. The New York Hospital Out-Patient Department uses a pressed paper board, 10 by 12 inches, which the patient rests on his knees.

THE SAMPLE STUDIED AND METHODS

Between April and October 1948, all patients except illiterate persons who newly entered the New York Hospital Out-Patient Department completed a C.M.I. The sample reported here consists of 179 consecutive patients attending the adult general medical clinic, a teaching clinic for fourth year students at Cornell University Medical College. These patients were examined, and their histories recorded, by forty-nine physicians on the staff of the Medical Department of the New York Hospital.

Since the data on the C.M.I. and those recorded by attending physicians in the medical histories were collected independently, it is possible to make valid comparisons. Each item answered on the C.M.I. was compared with each item recorded in the medical history and tabulations made in four categories: (1) items that appeared in both the C.M.I. and the history,

The work described in this paper was done under a contract, recommended by the National Research Council, between the Veterans Administration and Cornell University.

From The New York Hospital and the Departments of Medicine (Neurology) and Psychiatry, Cornell University Medical College, and Teachers College, Columbia University.

(2) items that appeared in the history but not in the C.M.I., (3) items that appeared in the C.M.I. but not in the history and (4) items in the history that elaborated data appearing in the C.M.I.

RESULTS

An average of 16.9 items of similar data were recorded in the C.M.I. and in each history (table 2). In addition, an average of 6.4 items were recorded in each history that did not appear in the C.M.I. However, only 1.4 of these were items of critical data about the present illness, the other 5.0 being routine quantitative historical data concerning such matters as

cance. The C.M.I. thus collected considerable information not included in the history.

Ninety-five per cent of the questions on the C.M.I. were answered identically in the C.M.I. and the history.

TABLE 1.—The Sections on the Cornell Medical Index

Section	Questions Referring to:	Number of Questions
A	Eyes and ears.....	9
B	Respiratory system	18
C	Cardiovascular system	13
D	Digestive tract	23
E	Musculoskeletal system	8
F	Skin	7

TABLE 2.—Average Number of Items Noted in Each Cornell Medical Index and in Each Hospital History*

	Average Number of Items			
	In Both C.M.I. and History	In History Only	In C.M.I. Only	In History Elaborating C.M.I.
Items answered affirmatively....	7.9	4.4	27.7	14.1
Items answered negatively.....	9.0	2.0	148.4	1.2
Total items noted.....	16.9	6.4	176.1	15.3

* The sample consisted of 179 patients.

the details of diet, the number of pounds gain or loss of weight, the number of siblings, data on the menstrual cycle, obstetric history, personal history and family history. The C.M.I. thus collected most of the critical data recorded in the history. In only 1 instance, a case of tuberculous cervical adenitis, the history gave information of crucial importance that was not found on the C.M.I., but which appeared in the C.M.I. supplementary sheet (described later).

The history also contained an average of 15.3 items of elaboration of data appearing on the C.M.I., for example, when the C.M.I. indicated the presence of chest pains, the physician noted its location, nature, onset, duration or radiation. These elaborations are, of course, important diagnostic criteria.

The C.M.I., on the other hand, contained an average of 176.1 items of data not recorded in the history. Of these, an average of 27.7 were answered affirmatively and so must be presumed to be of diagnostic signifi-

Fig. 1.—The percentage of patients with symptoms referable to the cardiovascular system (horizontal values), as indicated in the Cornell Medical Index and as noted in the hospital histories.

This corresponds closely to the agreement of two independent oral interviews with the same patient. Patients thus appear to answer printed questions in

Fig. 2.—The average number of C. M. I. items (vertical values) included in long and in short hospital histories. The horizontal row of figures at the bottom shows the number of words in the histories.

the C.M.I. as honestly and accurately as they do similar questions in interview. This was further confirmed by questioning more than 200 patients, after they had completed the C.M.I., about each of their responses;

it was found that if they could read the questions they almost always understood what was being asked and then answered accurately.

The symptoms appearing in the C.M.I. but not in the history are of special interest. A study was made of these in one section of the C.M.I. The cardiac section was chosen for study because the items of cardiac data recorded in medical histories are comparatively standard. In figure 1 are shown the number of patients who indicated symptoms in the C.M.I. referable to the cardiovascular system in comparison to the number in whose histories these same symptoms were recorded. In every instance more patients indicated symptoms in the C.M.I. than the examining physicians recorded in their histories. The histories must be considered deficient in these data. The value of filing the C.M.I. with the patient's medical records in situations like this is obvious.

The length of each history was compared with the number of items it contained that were noted on the C.M.I. Figure 2 shows that the longer the history the more data were included that appear in the C.M.I. The data in the C.M.I. are therefore those that physicians included in their histories, more being included when they wrote a longer history. The histories studied, like most others recorded in the best ordered hospitals, were especially deficient in information about the patient's emotions, there being an average of only 0.4 items in each history. The C.M.I., on the other hand, collects 51 items, of which an average of 7.8 were answered affirmatively. It is to be emphasized that to evaluate properly the patient's psychologic status it is necessary to know definitely which symptoms are absent as well as which are present.

THE SUPPLEMENTARY SHEET

In addition to completing the C.M.I., each patient was asked to fill out a separate sheet on which appeared the directions: "Write out all the troubles for which you come to the clinic." Because it was a record of the patient's own formulation of his illness, the information patients entered on this sheet was found to increase the usefulness of the C.M.I. Although 25 per cent of the patients did not write anything, 70 per cent indicated the chief complaint noted in the hospital history, 50 per cent wrote information that highlighted the C.M.I., that is, indicated which symptoms were most troublesome, and 30 per cent wrote information not otherwise found on the C.M.I. In most instances, this information contained additional data about the present illness. The C.M.I. and the supplementary sheet together usually included practically all the basic data, and some of the elaborations, in the hospital history.

Patients took from ten to thirty minutes to complete both the C.M.I. and the supplementary sheet. The time depended in part on their level of education, but for the most part on the ease with which they came to decisions. For instance, compulsive and depressed persons took longer than others to answer the questions on the C.M.I. More than 70 per cent of the patients with at least an elementary school education finished the C.M.I. in less than fifteen minutes and almost 90 per cent in less than twenty minutes.

Only rarely did a patient show any disinclination to fill out the C.M.I. Almost all completed it. As a matter of course, many, in fact, expressed

faction that the doctors were making as thorough an investigation of their medical problems as the varied and searching questions on the C.M.I. indicated. Although some patients found difficulty in formulating and writing out their complaints on the supplementary sheet, they found no trouble in answering the printed questions by circling a "Yes" or "No."

CASE HISTORIES

The value of the C.M.I. in calling attention to, and clarifying, aspects of the patient's disorder is illustrated in the following case histories. It is to be noted that during the course of this study the C.M.I. was not available to the examining physicians.

Patient's Symptoms Not Fully Described in the History.—T. O., a woman aged 43, sought medical advice for known hypertension and obesity. The medical history recorded by the examining physician did not mention the following symptoms of which the patient complained on the C.M.I.: chest pains, palpitation, tachycardia, dyspnea, ankle edema, cramps in the legs, headaches, dizziness, faintness and muscular twitching. Whether the physician did not elicit and record these symptoms because of lack of time, or pre-knowledge of the diagnosis, is not known. Nevertheless, it is obviously desirable to have them a part of the patient's permanent record. This could be done at no further expenditure of the physician's time by filing the C.M.I. with the hospital history.

An Important Item of Medical History Overlooked.—C. J., a woman aged 38, reported to the admitting clinic complaining of a "stroke" of three months' duration, with impairment of speech and right-sided weakness. In the general medical clinic, to which she was referred, she was examined extensively by a fourth year student and by an attending physician. Because she had hypertension in her lower extremities and hypotension in her upper, it was decided to admit her to the hospital for further study.

On the ward she was interviewed and examined by three physicians independently. Perhaps because her speech impairment made inquiry difficult, none of the five physicians who interviewed her obtained a history of syphilis, an item of crucial diagnostic importance. She had noted a history of syphilis on the C.M.I. on her first visit to the admitting clinic. Not until the result of her Mazzini test was reported positive did the staff elicit her history of syphilis. Had the C.M.I. been available to the examining physicians, to call attention to the past history of syphilis, the final diagnoses of syphilitic aortitis, central nervous system syphilis and cerebral vascular accident would have been facilitated.

An Important Emotional Disorder Overlooked.—O. K., a man, aged 70, sought medical help because of urinary complaints. A diagnosis of benign prostatic hypertrophy was made in the urology clinic, and the patient was admitted to the hospital for treatment. During his forty hours in the hospital, on his chart by two physicians, only one note about his emotional state was made. The nurse who stated that the patient was nervous about operation, complained of the admission to hospital, and was abruptly terminated by being put out of the

bathroom window and falling nine stories to the ground. He was instantly killed.

A subsequent review of the C.M.I. he had completed on his first visit to the hospital showed that he had indicated eighty-five symptoms in addition to his urinary difficulties. Many were indicative of an emotional disturbance. He complained of such symptoms as feeling unhappy and depressed, being keyed up and jittery, having frightening thoughts coming to his mind, life looking entirely hopeless, and often wishing he were dead and away from it all. Obviously, had the C.M.I. been available to the staff physicians, attention would have been directed to the urgent need for psychiatric appraisal and treatment, and it is not unlikely that prompt measures, including psychotherapy, might have prevented the suicide.

The Importance of the Patient's Total Medical Problem Overlooked.—G. R., a man aged 34, complained of loss of vision in the right eye. He was referred by the admitting physician to the ophthalmology department for immediate consultation. He was seen there the next day, where a diagnosis was made of right optic atrophy, due either to spasm of the central retinal artery or to other occlusive disease, such as syphilis. The day after he was seen in the general medical department, where additional diagnoses were made of inactive rheumatic heart disease and atopic dermatitis, with a history of paroxysmal tachycardia, a history of prostatitis and possible hysterical reaction. That afternoon he was seen in the dermatology department, where the diagnosis of atopic dermatitis was confirmed. His next visit was again to the dermatology department, ten days later, where a diagnosis of neurodermatitis was made. The following day he was seen in the ophthalmology department; no further diagnoses were made, but the use of amyl nitrite was recommended. Eight days later the patient again visited the ophthalmology department, where one physician noted on the history, "Patient wants psychosomatic care, or at least evaluation, and I think it a worth while idea; in view of precipitation of all attacks when under tension and a probable organic etiology, I do not know how much good it will do." Six days later the patient was seen in the neurology department, where diagnoses were made of right optic atrophy, due to vasospastic phenomenon, and severe emotional problems. The next day, twenty-eight days after his initial visit to the admitting clinic, the patient was seen for the first time in the psychosomatic department. There, on investigation, the close relation of his ocular disorder to other bodily symptoms and to his emotional disturbance was recognized.

This relation, typically found in such ocular disorders, was indicated by the patient himself on his first visit to the hospital. In the admitting clinic, he had indicated on the C.M.I. eighty-seven symptoms in addition to the three about his eyes, many suggestive of vasomotor disturbances in other parts of his body and many outlining a severe emotional disorder. In addition, he wrote on the C.M.I. supplementary sheet, "I am afraid, or rather I don't seem to care about anything any more. I can't breathe, I feel hungry but I don't want to eat. I make dates and promises (in all sincerity) but hate to keep them—and at the same time I want to. I feel that I am about to become totally blind (I have been on several occasions). I want a girl,

but I'm afraid to take the steps to get one. I have lost all interest in my talents, which are art, music (my hearing dims from time to time), science—as I write about them I feel enthusiasm, but if I follow my impulses, which is to leave and try again, I know that I won't follow through. I have no skills and no real job—I work for a commission and live under the constant harassing of my mother, who is slowly driving me mad. She criticizes me on my habits and is responsible for my being here, as she has preached psychology to me for years."

Obviously, if the C.M.I. and the supplementary sheet had been reviewed by the physicians who examined the patient, it would have been impossible to overlook the strong suggestion that the ocular symptoms were not an isolated medical phenomenon, but only one manifestation of a generalized systemic and emotional disorder. The patient might then have been referred immediately for comprehensive evaluation and treatment of his total problem, instead of this being postponed for a month while only a single aspect of his disorder was being considered.

COMMENT

In investigation of the medical value of the data it collects, the C.M.I. was compared with recorded medical histories; this comparison was made with the knowledge that such histories are open to criticism, because the items included have been chosen empirically. However, no better criterion for the diagnostic value of general medical data exists than those chosen for recording in medical histories of a university teaching hospital. As shown previously, the data collected by the C.M.I. include those recorded in these general medical histories in addition to many others of diagnostic importance.

Until a statistical method of scoring is formulated, the C.M.I., like medical data on a hospital history, is interpreted by clinical evaluation. Interpretation is facilitated because the affirmative responses, indicating the presence of symptoms, are conspicuous. The physician can quickly note which symptoms the patient has and how many, in each section of the C.M.I., and so can form a tentative evaluation of the patient's medical problems. Interpretation of the C.M.I. is, of course, more searching after the patient's affirmative responses have been elaborated in interview.

Most of the data on hospital histories and on psychiatric forms of the Cornell Index are to be found on the C.M.I., and valid somatic and personality appraisals are often possible with the use of the C.M.I. alone. However, the C.M.I. is intended only as an adjunct to, and not a substitute for, oral interview.

The C.M.I. has been found useful in medical clinics, in specialty clinics, in teaching, in industry and in the private practice of general and internal medicine. The time-saving features of the C.M.I. recommend it for use in military induction stations, in military hospitals and in Veterans Administration clinics and hospitals.

The C.M.I. has the following facts to recommend it:

1. The physician is not burdened with the task of asking the 195 questions on the C.M.I. and recording the answers, in addition to elaborating the present illness and items of past history. The questions patients have already answered in the negative on the C.M.I. need not be repeated in interview.

2. It orients the physician, even before he sees the patient, with a rapid survey of the patient's total medical problem and suggests immediately what matters need investigation. After acquaintance with the C.M.I. it is possible to review it in as little as one minute.

3. Since the questions are identical for each patient, comparisons of the responses among individual patients are valid, a value important for research.

4. In teaching, the standardization of the data and their systematic arrangement facilitate study and comparisons among patients.

The most effective technic for use of the C.M.I. as an adjunct to interview has been found to be for the patient to complete the C.M.I. before he sees the physician and for the physician to review the C.M.I. before he interviews the patient. The physician thereby gains a background of knowledge about the patient to orient him in interview.

When first using the C.M.I. some physicians conduct medical interviews according to their established routine. However, inquiry need consist only of eliciting the details of the present illness and asking the patient to tell more about the symptoms he indicated on the C.M.I. and supplementary sheet. In telling more, patients usually reveal important relations of their symptoms to other complaints and to life situations. This technic of history taking is not unformulated and time consuming, as may first appear. Discussion with the patient of his responses to the questions about his psychologic status usually leads directly to a discussion of his emotional problems and life situation and to the establishment of a good physician-patient relationship.

SUMMARY

The Cornell Medical Index, a self-administered form, was constructed to obtain important facts about a patient's medical history for comprehensive diagnostic and prognostic appraisals, at no expense of the physician's time. Most of the data physicians recorded in the histories of patients in the Medical Department of the New York Hospital, and, in addition, a large body of supplementary data, were collected by the Cornell Medical Index. These data were collected as accurately as in oral interview. The Cornell Medical Index has been found to be of use in hospitals, in teaching, in industry, in private practice and in research and would appear to offer aid to physicians in military induction stations and Veterans Administration hospitals.

In these situations the Cornell Medical Index has been found to be useful because: It collects for appraisal a large and comprehensive body of information about the patient's medical history at no expenditure of the physician's time; it facilitates interview by making available to the physician a preliminary survey of the patient's total medical problems; its data, being systematically arranged, are easier to review than those on conventional medical histories, and, by calling attention to the patient's symptoms and significant items of past history, it assures that their investigation will not be overlooked because the physician lacked time to elicit them.

Ireland has cut its population in half during the last hundred years (partly by means suggested by Malthus) and has improved its level of living from one of the lowest to one of the highest in Europe.—Guy Irving Burch, *Population Bulletin*, April 1949.

Council on Pharmacy and Chemistry

REPORT TO THE COUNCIL

The Council has authorized publication of the following statement from the Therapeutic Trials Committee, a standing committee of the Council on Pharmacy and Chemistry.

AUSTIN SMITH, M. D., Secretary.

METHODS OF CLINICAL STUDY AND EVALUATION OF THERAPEUTIC AGENTS IN POLIOMYELITIS

Early in 1947, the Therapeutic Trials Committee was asked by the National Foundation for Infantile Paralysis to investigate the feasibility of and methods available for evaluating the effect of moist heat in the treatment of poliomyelitis. A subcommittee was formed which, together with a number of consultants, studied this problem for nearly two years. Although a report was rendered to the National Foundation outlining in detail the methods which, in the opinion of the subcommittee and its consultants, should be used in evaluating the effect of this modality in poliomyelitis, certain principles applicable to the evaluation of any agent in this disease became evident from these studies. It was thought desirable to present these principles in the form of a report in the hope that they will prove useful to any who may be charged with the task of testing the effectiveness of some new agent in this disease.

WALTON VAN WINKLE JR., M.D., Secretary.

Before selecting methods for the evaluation of any agent in the treatment of a disease, the ultimate effect that is desired must be clearly in mind. In the case of poliomyelitis, four possible results of therapy may be produced by an effective agent: (1) alleviation of symptoms during the acute phase, such as pain, muscle "stiffness" or "spasm"; (2) prevention of paralysis; (3) prevention of death, and (4) more complete restoration of full muscular function. In this report, attention will be focused on the first two and the last of these effects, since death from poliomyelitis results from specific localization of the disease, either bulbar or affecting the innervation of the respiratory muscles.

The basic problem in evaluating any therapeutic agent in a disease such as poliomyelitis is to overcome or diminish the errors introduced by the wide variations in the spontaneous course of the disease and the inability to predict the probable outcome of a given case when seen early in the disease at the time therapeutic measures are instituted. In order to understand the reasons for the recommendations contained in this report, it is necessary to appreciate these variables, and, therefore, a brief discussion of the more important ones is presented.

VARIABLES TO BE CONSIDERED

The Diagnosis of Poliomyelitis.—The diagnosis of poliomyelitis must be based primarily on symptoms and clinical findings. The earlier in the disease a case is seen, the less characteristic these are. In addition, certain laboratory observations are of value, but none which is available to the clinician is absolutely diagnostic. The committee believes that for the purpose of evaluating a proposed therapeutic agent, the following diagnostic criteria should be met:

1. The history of onset and course must be compatible with poliomyelitis; i.e., acute onset of a febrile illness, sometimes resembling influenza, with headache, fever and a recognizable stiff neck as determined at least by some disinclination to forward flexion of the head. Vomiting may, or may not, be present.

The Subcommittee on Poliomyelitis consisted of Dr. William T. Green, Boston, Chairman; Dr. Hugo Muench, Boston; Dr. Derek Denny-Brown, Boston, and Dr. James L. Wilson, Ann Arbor, Mich. Consultants to the Subcommittee: Dr. Montgomery Blair, Washington, D. C.; Dr. Edward Shaw, San Francisco; Dr. Frank E. Sutton, Richmond, Va.; Dr. John A. S. Wall, Washington, D. C., and Dr.

2. The fever should rarely exceed 104 F. and should not persist longer than six days, unless obvious secondary complications are noted or bulbar palsies develop.

3. If no paralysis is present at the time of admission, there must be a fever and an abnormal spinal fluid with a range of cell count between 10 and 500. The protein content is elevated and the sugar content normal.

4. Cases of paralytic disease seen during the febrile period should show a localized paralysis that is definitely demonstrable and not a diffuse generalized weakness.

5. For a proper evaluation of therapeutic measures, cases first seen after the twenty-eighth day of the disease should not be admitted to the study.

It is appreciated that the foregoing criteria will result in the exclusion of some cases of poliomyelitis, but they will also prevent the inclusion of many cases of other diseases which, in the initial stages, may be mistaken for atypical poliomyelitis, particularly during an epidemic. These criteria are recommended, therefore, as a means of decreasing the influence of one variable in the study.

The Course of the Disease.—Poliomyelitis shows extreme variability in its course; on one hand, a patient may show extensive muscular involvement during the acute stage but have no residual paralysis or weakness at the end of eighteen months; on the other hand, a patient with only minor involvement at the onset of the disease may become a hopeless cripple. In some patients paralysis never develops, and others show remarkable spontaneous recovery from seemingly severe paralysis. It must be emphasized that at present it is not possible to predict the eventual outcome of a case of poliomyelitis by any tests or examinations made during the acute or early convalescent phases of the disease.

Since it is known that a large number of patients showing severe involvement during the early stages of the disease recover spontaneously, any method of evaluation of a therapeutic agent must be so designed as to take into account this spontaneous improvement and not credit the agent with this result.

The tendency to spontaneous improvement not only affects the evaluation of the final results of therapy but also affects the evaluation of the agent from the standpoint of relieving symptoms and shortening the course of the disease. For instance, it is difficult, in the acute phase, to distinguish between the pseudoparalysis of pain and the actual paralysis due to nerve cell involvement. It is impossible to determine whether the functionless anterior horn cell, as manifested by a paralyzed muscle, is a destroyed cell or is one which will recover.

Variations in the Virus.—It is now known that there are at least three immunologic types of poliomyelitis virus.¹ Whether or not these different, although related, viruses are responsible for the differences in clinical course of patients with poliomyelitis in one epidemic as compared with those in another is not known, nor is it known whether different viruses will respond differently to therapeutic agents. Thus, any evaluation of such agents should be made in a manner that will be most likely to include patients with various types of viruses utilizing different seasons and geographical source.

Variations in Geography.—It has long been noted that poliomyelitis is most prevalent in the late summer months but in certain localities tends to occur throughout the year. Certain other characteristics associated with geographical distribution have been suggested, and, therefore, this factor must be considered in the evaluation of any therapeutic agent.

Age Distribution.—Poliomyelitis formerly was primarily confined to the youngest age groups. In recent years a higher proportion of older persons have been affected. Reliable data are not available which would indicate whether the course or outcome of the disease differs in the various age groups. It is essential, therefore, to consider the age factor in designing a study of the treatment of the disease.

Differences in Time.—It has been noted that various epidemics observed in different years vary not only in the geographic

distribution of cases, but also with respect to the severity of the disease and the incidence of such forms of poliomyelitis as the bulbar type. Whether this is due to differences in types of the virus or to other factors is not known. It is important, therefore, to observe both control cases and cases in which the agent is tested at the same time in order to eliminate this difference. An excellent discussion of the importance of the general factor of time and other factors which may influence an investigation has been given by Albritton²; those planning to undertake clinical investigations should refer to these discussions.

Methods of Appraising the Condition of the Patient.—Poliomyelitis does not lend itself readily to quantitative study. Reliance must be placed on the subjective response of the patient in the evaluation of pain and tenderness, on semiquantitative muscle examinations in the evaluation of progress and extent of specific muscle involvement and on deformity and function for the over-all end result of treatment. In all of these, the judgment and experience of the person making the examinations provide an imponderable variable in any evaluation of a therapeutic procedure.

PROPOSED DESIGN OF INVESTIGATION

It is obvious from the brief discussion just presented that any study designed to evaluate a therapeutic agent in a disease the nature of which is as variable as poliomyelitis must be rigidly controlled if it is to have any value. Because of these variables, it is also apparent that a large number of cases will have to be studied simultaneously at various clinics, well distributed geographically. Because of differences in diagnostic criteria, age distribution of patients admitted, economic level from which patients come and methods of examining muscles and evaluating function among different clinics, any study involving more than one institution will have to be conducted in a collaborative manner. It would seem wise, therefore, to outline briefly the opinion of the committee with regard to the conduct of a collaborative investigation.

Collaboration of Several Clinics in Evaluating a Therapeutic Agent.—In general, there are three principal ways in which a collaborative investigation may be organized. An individual or small group may devise the details of the project, secure the cooperation of a number of investigators and direct the project from a central headquarters. The investigators have no voice in planning, operation or evaluation of the investigation but serve merely as agents of the central group. A second method involves the collaboration of various groups, each carrying out an investigation of its own choosing but exchanging and pooling information. No central planning group is involved and each clinic maintains its autonomy. The third method, a compromise of the first two, involves joint planning by all collaborators with a central group to execute the decisions and maintain uniformity of procedures. The central group makes no policy but merely carries out the decisions agreed on by the collaborators.

It is the last method that, in general, is most practical and at the same time reasonably efficient and is the one probably best suited for thorough evaluation of therapeutic agents in poliomyelitis. Each investigator must be convinced of the soundness of the project and understand fully the reasons for any restrictions of the investigation or procedures to be followed. This is secured by joint planning. On the other hand, some of the procedures which must be employed require central direction, as will be evident later, and this can be secured by the establishment of a central executive group.

It is important that, before embarking on any collaborative investigation, all details of methods and procedures be agreed on by all participants. Once agreed on, it becomes the duty of the central executive group to insure that these methods and procedures are followed. Finally, the central group should be responsible for the collection of records for analysis and providing a rapid interchange of information. A scheme similar to this has been used in developing the methods which will be outlined.

Selection of Participating Clinics.—The prime requisites for participation in any collaborative investigation of the value of a therapeutic agent in poliomyelitis are the following: (1) quali-

1. Kessel, J. F., and Pait, C. F.: Differentiation of Three Groups of Poliomyelitis Virus, *Proc. Soc. Exper. Biol. & Med.* **70**:315 (Feb.) 1949. Bodian, D. W.: Poliomyelitis: Another Strain of the Lansing Type, *ibid.* **70**:1 (Jan.) 1949. Roberts, E. C.: A Flocculation Test as a Possible Method for Differentiating Immunologic Types of the Poliomyelitis Virus, *Pub. Health Rep.* **64**:212 (Feb. 18) 1949.

2. Albritton, E. C.: *Experimental Design and Judgment of Evidence*, Ann Arbor, Mich., Edwards Bros. Inc., 1948.

fied physicians, experienced in the diagnosis and treatment of the disease in all its manifestations; (2) qualified medical ancillary personnel experienced in the care of patients with poliomyelitis; (3) facilities and technical staff adequate to carry out procedures in excess of those usually used in the routine treatment of patients with poliomyelitis, and (4) a probable case load sufficient to provide adequate clinical material for study.

Number of Participating Clinics.—The number of clinics participating in a collaborative effort should be sufficient to insure the admission of 750 to 1,500 cases suitable for study within a two year period. The clinics should be well distributed geographically for reasons mentioned previously. An excessive number of participants makes the project unwieldy and may tend to introduce additional uncontrolled variables. It is believed that in a study of this character ten to fifteen clinics would be an optimum number.

Acceptance of Cases to Study.—Cases must be accepted by all participating groups in accordance with uniform criteria. These have already been discussed and do not need repetition here. On admission, the exact stage of the disease in each case should be noted, and in particular the precise time of onset of fever should be determined.

Controls.—Because of the great variability of the clinical course of poliomyelitis and because of the impossibility of making an accurate prognosis in a given case, it is essential that any group of patients treated with a new agent be compared with another group of patients exactly comparable in every respect except that the agent under investigation is omitted. To do this is not as simple as it would seem. A group of patients treated at one clinic cannot be compared with a control group seen at another clinic. Differences in the details of care of the patients, environmental surroundings, climate and many other factors cannot be made identical for the two groups. It is important, therefore, that the two groups to be compared be formed at each participating clinic.

Extraordinary care must be exercised in assigning cases to the test group and to the control group to insure exact comparability of the two groups. In order to minimize those differences which might occur because one patient is admitted on the first day of the disease and another on the twentieth day of the disease, a scheme of classification or "stratification" of patients must be adopted before assigning them to control or test groups. In the discussion of diagnostic criteria, it was recommended that no case seen after the twenty-eighth day of the disease be admitted to the study. It is recommended that those cases seen before the twenty-eighth day be grouped as follows: (1) pre-paralytic cases seen during the febrile illness; (2) paralytic cases seen during the febrile state up to seven days after the onset of the disease; (3) paralytic cases seen from the eighth to the twenty-eighth day after the onset of the disease.

The day of onset is considered as the day on which fever first appears. Control and test groups are to be formed within each of these three groups of patients.

It is recognized that the proposed stratification is crude and that each group will include cases of widely varying severity and clinical course. Although it might be desirable to make more restricted classifications and thus reduce the variability within each group, such refinement does not seem to be practicable unless it is known that each clinic will handle an extraordinarily large number of patients; otherwise the groups will be too small from which to form adequate control and test subgroups. The purpose of this procedure, however, is to insure that the control and test groups contain patients in approximately the same stage of the disease when the test procedures are applied.

The scheme of stratification may have to be modified, depending on the type of agent being studied. For instance, an antibiotic should be tested only during the acute febrile stage, since, presumably, the virus is no longer active in the disease after that time. It might be important in such circumstances to establish classifications or strata for short time periods; i.e., eighteen, twenty-four and thirty-six hours after onset.

The cardinal principle in assigning patients to either the control or the test group is that the assignments must be made in a completely random manner.² This means that such assign-

ments must not be made in any systematic fashion. This requirement precludes the assigning of alternate cases to the control or test groups. Several schemes may be used to secure the desired randomization such as tossing a coin or drawing straws. The scheme proposed here is not considered to be better than other methods of randomization, but may have certain advantages from an administrative standpoint. It also insures that a uniform system is used by all clinics collaborating in the investigation. It is adopted from a method used in the British Empire Cancer Campaign, an investigation of estrogens in cancer.

Three books, corresponding to the three classifications of cases, are provided each clinic. These books contain lines on which the names of the patients are written in consecutive order as they are admitted and assigned a classification. Each line has previously been identified with a letter, C or T, indicating that the patient whose name falls on that line is to be assigned to the control or the test group.

The assignment of the letters T and C to the lines is performed by the central executive group in the following manner: Ten black balls and ten white balls are placed in a box and are removed one at a time by a blindfolded person. If a black ball is removed, a T is entered on a line; if a white ball is removed, a C is entered on the line. This operation is repeated until all lines in all books have been marked.

This procedure insures that the assignment of letters, and hence cases, is done in a random manner and also insures that in every twenty consecutive admissions 10 patients will be assigned to the test group and ten assigned to the control group. Thus one group can never exceed another by more than 10 cases.

The books should be kept so that the admitting physician who determines the data (time of onset, presence of localized weakness) on which the patient is classified never knows whether the incoming patient is to be assigned to the control or the test group.

Treatment of Patients.—It is of the utmost importance that both the test group and the control group of patients receive identical treatment with the one exception that the patients in the test group have added to their treatment the agent under investigation. Furthermore, it is important that the effects of the agent being tested be not confused with the effects of other therapeutic procedures. This requirement imposes certain technical and psychologic difficulties which merit discussion.

Only in diseases which are self limited and in which complete recovery can be expected without therapy is it permissible to compare a test group of patients with a control group receiving no treatment. Poliomyelitis is certainly not a disease in this classification. On the other hand, there is not now a universally agreed upon method of treatment, and it is exceedingly difficult, therefore, to devise a basic form of therapy, acceptable to all workers, adequate for the patient and at the same time of such a nature that comparison of patients treated by this regimen with those receiving some form of therapy can be depended on to demonstrate significant differences in results should the agent under investigation be effective.

No form of therapy of poliomyelitis in use today, except such procedures as tracheotomy or use of a respirator in certain forms of the disease, has been conclusively proved to be superior in end results to those observed in patients with no treatment. Even the value of tracheotomy is disputed. This, of course, does not refer to orthopedic procedures to correct deformity. Also, this does not mean that certain forms of therapy may not produce superior results, but the critical test has never been performed in an adequate manner. There is not, therefore, a generally accepted basic treatment for the disease. For instance, hot pack therapy as advocated by Sister Kenny as part of her treatment is used in comparatively few places, although many modifications are in use. Physical therapy procedures have not been standardized and vary markedly from clinic to clinic.

Unfortunately the public has become aware of certain procedures under the name of their original protagonist without knowing precisely of what those procedures consist. Public opinion has, in a number of instances, forced the adoption of costly treatment procedures against the better judgment of the responsible physicians and without adequate proof that such procedures are advantageous or superior to others advocated by more rational minds.

These factors make the adoption of a so-called basic treatment on which the therapeutic agent under test can be superimposed a difficult task. On the one hand, the treatment must be simple and easily standardized, and on the other hand it must satisfy the physicians, patients and the patients' relatives.

Because of this pronounced public opinion regarding treatment of poliomyelitis, some physicians and some physical therapists have formed strong convictions regarding treatment methods, based more on emotion than on scientific evidence. This emotional feeling may tend to introduce bias on the part of the physician and inadvertent or intentional differences in application of treatment procedures by physical therapists to patients in the control group as compared with the procedures used in the test group. Constant awareness of this possibility is necessary in order to avoid interference with or destruction of the design of the investigation.

It is also apparent that the precise details of the treatment procedures employed in both control and test groups will depend to some extent on the nature of the therapeutic agent to be tested. For instance, in the problem originally presented to the Therapeutic Trials Committee, moist heat was the agent to be tested. This precluded the use of hot packs, or for that matter, heat in any form, in procedures for the control group. If a drug were the agent to be tested, it might be possible to include heat in the basic treatment but might mean the exclusion of other drugs. It is necessary, therefore, in designing an experiment of this character to eliminate from the basic treatment any procedure or agent which would tend to confuse or augment the possible actions of the agent being tested. For these reasons it is not possible to outline in detail recommended basic treatment procedures, but certain aspects of treatment can be mentioned.

It is important to emphasize again that whatever basic treatment is adopted, both the control and test groups should receive this treatment in an identical manner. Furthermore, since any treatment of poliomyelitis involves manipulation of the patient, the personnel administering the treatment should each handle an equal number of patients in both test and control groups in order to minimize the effects of personal differences in technics.

It seems generally agreed that certain physical therapy procedures should be instituted early in the treatment of patients with poliomyelitis. The nature and extent of these procedures vary considerably among hospitals, and it is important that before embarking on a collaborative investigation agreement be reached among all participants regarding the detailed methods to be used and the frequency and duration of application to cases. Furthermore, physical therapy is applied by physical therapists whose training and experience vary in different institutions. No written directions can be prepared which would be wholly satisfactory for the standardization of such procedures. It should be apparent that such standardization is important in order to minimize a major variable which might affect the results of the investigation. If a drug is being tested, both the test and the control groups should receive the same symptomatic care for relief of pain and for maximum comfort.

The committee believes that the most satisfactory method of achieving standardization of physical therapy procedures to be used in treating patients included in a collaborative program would be to have the principal physical therapists from each collaborating institution brought together at one institution equipped to teach them the procedures agreed on by the investigators. The suggested training period for these physical therapists should be four to six weeks in duration and the training should be given not too far in advance of the contemplated time of starting the investigation. Training should be given under the direction of a competent physiatrist or orthopedic surgeon and a qualified physical therapist.

In order to insure that the standardization of procedures is maintained throughout the investigation, the personnel responsible for giving the original training should visit the collaborating institutions at intervals during the investigation, observe the procedures in operation and correct any departures from agreed technics. This activity is of importance, since it is likely that the duration of the investigation may be prolonged, depending on the number of cases available. The possibility of unconscious variations in technical procedures among the various institutions involved in the program must be guarded against.

If the application or administration of the therapeutic agent to the test group involves manipulation of the patient or necessitates some concomitant procedure, such manipulation or procedure must be given to the control group in exactly the same manner with the exception that the agent itself is omitted. It would be advisable, for instance, if the agent were a drug requiring frequent injection, to administer a "blank" or an injection of the vehicle at precisely the same intervals to the control group.

The question of when patients should be discharged from the hospital to the outpatient clinic is a difficult one and should be decided in advance of the investigation. The principle to bear in mind is that both the control and test groups be treated alike in this respect. This means that should it be decided that patients will be discharged at a certain stage of convalescence, all patients, in both the control and the treated groups, should be discharged at that stage of the disease.

The duration of observation of patients included in an investigative program should be sufficiently long for any spontaneous recovery to become fully apparent. In general, there seems to be no evidence that natural recovery extends beyond sixteen to eighteen months after the onset, and it is suggested that final examination of each patient be made eighteen months after the onset of the disease.

EVALUATION OF RESULTS

In a disease such as poliomyelitis the end results in a given patient cannot be appraised without an accurate knowledge of the extent of the original disability and the progress of the recovery. In the evaluation of the extent of the disease and

Grade as Used by National Foundation for Infantile Paralysis		Definition
Grade 0	0	No palpable contraction
Trace or 1	1	Palpable contraction of muscle, but no motion of the part which the muscle should move
Poor — or 2	2—	Muscle will move part, but not against gravity and not through a full range
Poor or 3	2	Muscle moves the part through its range, but not against gravity
Fair — or 4	3—	Muscle will move part against gravity, but not through a full range
Fair or 5	3	Muscle will carry part through its range of motion against gravity, but not against added resistance
Good or 6	4	Muscle will lift part against gravity and added resistance, but lacks normal strength
Normal or 7	5	Normal strength

the degree of residual paralysis at the end of observation, reliance has to be placed on manual muscle examination. Unfortunately, manual muscle examination is not a procedure which lends itself readily to quantitative evaluation and the factor of judgment of the observer plays an important role in the interpretation of results. Furthermore, some muscles can be examined and their functional capacity determined more readily and more accurately than others. Poliomyelitis is frequently, if not always, selective with respect to the muscles affected, and it is seldom, if ever, possible to find 2 patients with the same muscles involved to exactly the same degree. It is not possible, therefore, to design an experiment wherein one patient may be paired with another for purposes of comparison.

Muscle Examinations.—The first muscle examination of each patient should be made as early in the disease as possible. It is probably not feasible to make an adequate examination during the acute febrile stage, but a complete examination should be commenced within forty-eight hours after the fever has subsided and, depending on the condition of the patient, carried out in piecemeal fashion over a period of several days. Examinations should then be made at monthly intervals after the onset of the disease during the first six months, at two month intervals during the second six months and at the fifteenth and eighteenth month after the onset of the disease.

It is not within the province of this report to detail the precise methods to be used in making muscle examinations. It is important, however, that the same methods be used on every patient in all participating institutions. This will be discussed in more detail later. The methods used should permit a semi-quantitative grading of the functional capacity of the muscle, and the committee recommends that some such scheme as the one shown in the accompanying table be used in assessing and recording the function of each muscle tested.
